Hi Chris

Thanks for the reply.

Yeah, I never ascribed any practical use to the "CP by spinning". But,
there are some fundamentally good thoughts generated here. For instance, I
can easily see why two dipoles rotating at the same rate and rotational
direction will couple *nothing*. Thats like trying to receive RHCP with a
LHCP antenna.
I have lived a long time without understanding Poynting and Maxwell
(almost 100 years older than me), I wouldnt want to change that now.

You are speaking of the specs on the USB card, I am speaking access point ... and actually, I have never searched for power-throttling in the USB card, I simply would not use it ... when the wife and I go out and I search for APs, I want every possible mw in action, at a clients, hotel, hospital, etc.

>> Having one side of transmission link error free is MUCH superior to have

No problem. I don't live in a dorm, trailer park, high-rise or apartment building ... the software will automatically adjust to find the best chan and recheck this decision, from time-to-time. If others don't have that capability, they may wish to upgrade ... like I have strongly implied, already, "If your AP is crap, toss it out!" I can't imagine anyone here who failed to read specs before purchasing, however ???

The equip can do b/g/n (b&g for the usb card in question, multiple computers here) With a windows widget to monitor my ap/card connection (transfer rate, errors, signal strength, etc.), I see it rise and fall from time to time. Sometimes I have seen the connection renegotiate from n to g to b ... however, at this same time AirSnare has went nuts. Seems wardriving teens are to blame ... <grin> I was a teen once, so long ago, I fear I may forget ... :-(

But, I will tell you, if ever I notice a problem with the errors (just looked, 3 errors), I will remember your words.

> Meanwhile, you're operating an alligator, jamming 56 times as many

Although, I am sure one or two of my neighbors are savvy enough to set their routers into non-broadcast mode of the SSID, and have WPA and filter on mac addresses, I just don't see the traffic/jam you speak of. But, like I say, if I do, I shall remember your words.

No, I would NOT. When I take my laptop and USB antenna analyzer out to
the antenna(s), I appreciate my omni. When I take my laptop and USB ODB
II out to the car (in another direction), I appreciate my omni. When
teens go by wardriving and trigger AirSnare warnings (and giving me
one-hell-of-a-kick!), I appreciate my omni. You hang around with the
old men here, beware the cynicism, it IS contagious!

Beware. Again you risk being controlled by the control freaks here.
Glad it works for you, attempt to enforce it for me, we have a battle
... you know, there is equip and hacks available to open up chans far in
excess of what is legal, I am sure some are savvy and use them ...
perhaps teenagers? <straight face> I have even heard of some flashing
their ap/cards with the foreign version of the software for them and
exceeding power/chans ... shame on them! :-|

However, you provide good discussion, and have valid arguments, I am
sure--some will agree with and appreciate--perhaps even some which are
state-of-the-art!

Personally, I would NEVER suggest purchasing an AP/card with less than
350mw capability. And, only then if you get one-hell-of-a-buy.

Warm regards,
JS

Mike,
I see no end to the present trend. A few decades ago GE here in
Bloomington started moving its manufacturing products overseas
only later to sell as they moved away from manufacturing and into cash
handling businesses such as banking, tv and the like..
Bloomington had a couple of plants making vacuum cleaners, they
moved out to Mexico. Beich's candy was sold to a Swiss company
Also had a major switch yard on the railroad which is now a waste
land.Result We paid for Mitsubishi to settle here to make cars.
Insurance companies got bigger here churning money and now import
Indian software people as they state american programmers do niot come
up to
par. The city commerce department encouraged hotels to be built
together with the import of 10K mexican workerst6o keep them clean and
hospitals became larger as immigrant births ballooned as insurance
against deportation which then increased taxes for bilingual
education.
All this because we moved away from letting the existing market
decide as we went global knowing that american ingenuity was the
answer to all.
Now Universities are getting failing grades thro out the country where
their products were intended to be the savior of capatalism which has
now changed
as entrepreneurs changed the "market" instead of strengthening the
infro structure. Now the motor industry wants feed money to continue
to build cars
with high labor content that cannot compete. So the idea of let the
"market" decide has now also disapeared as we nationalise/take over
our industries.

Americas answer? Pull away from the dissemination of science and try to remold the World (market) to match our needs. Suppression of the meagre results in universities is such a small dent in the overall picture. But all knew what the total end effect would be. History shows that all that seek an empire
always over estimate their abilities to retain what their military had won such that another new empire emerges.To increase market size while decreasing
population wealth eventually only leads to total domination or widespead civil strife.
Greed is a terrible thing
Pull up the ladder Jack. To heck with the others i'm O.K. and that's the most important thing for today. Tomorrow is another day

You MUST take into consideration every single mm of the loops length!
Leads (apparently "pigtails") ARE the loop ...

But, nothing stops you from being creative. The guy whos'
construction(s) we are following did have about optimum parts to work
with--you will just have to be "creative" ... good-luck.

Warm regards,
JS

Hi Chris

I am having a block in my learning. As I understand it, this would
actually happen if it could be performed.

A spinning dipole would require more power to spin it if it had DC on it
than if it had no DC on it. And, actually, it would require no power to
keep the dipole spinning since there would be that theoritical vacuum around
it. But, once you apply the DC, power would be required to keep it
spinning. That amount of added power would be determined by the amount of
DC applied. Do you confirm that this is true?
My question relates to my ignorance about what there is in the "vacuum" to
cause "drag".

Yes - as I said, the means of spinning the dipole would be the counterpart
to the 'transmitter'

> And, actually, it would require no power to keep the dipole spinning since
> there would be that theoritical vacuum around it.

If you say so - you're specifying a hypothetical zero-friction system which
is but one of several possible scenarios.

> But, once you apply the DC, power would be required to keep it spinning.
> That amount of added power would be determined by the amount of DC
> applied. Do you confirm that this is true?

Certainly work would need to be done to spin the dipole and create the
outgoing wave by virtue of its rotation. I suppose it follows that the
strength of the outgoing wave would be proportional to the applied voltage
but I'm not certain that a greater voltage would require more mechanical
work to spin the dipole - you may be right but I'm not certain I can confirm
this from what I think I know!

> My question relates to my ignorance about what there is in the "vacuum"
> to cause "drag".
>
> Jerry KD6JDJ

I'm afraid I had taken very little account of causes of mechanical drag. As
noted before, this was a thought experiment - the sort of thing that can
reach a useful conclusion (i.e. 'not likely' in this case!) without
requiring detailed examination of what may be 'second-order' influences.

Just research 'solar sailing' if you want to read about a phenomenon that involves 'drag' in a vacuum on account of a flux of photons. It's used to help keep satellites 'on station' whilst saving hydrazine.

Hi Chris

I accept as valid, your statement that the dipole with DC will radiate a far field when spun. I have a mental block related to questioning what makes it harder to spin when the DC is increased.
Yes, I do consider the media in which the dipole is spinning creates no friction. I do wonder what makes it harder to spin when the DC voltage is increased.

Jerry

<assemblywizard@gmail.com> wrote:

>You see millions of cell phones; You see a LOT of problems?

Oh yes, I certainly do see problems. They're well hidden and
mitigated in various ways. For example, if the error rate climbs, the
adaptive tx power control cranks up the power on both the handset and
the cell site end. If it persists, you get disconnected. Rather than
have the user sound like they're talking while gargling ball bearings,
the cell site just pulls the plug. Incidentally, the tx power control
algorithm is rather messy as it has to handle different data types, at
different rates, all while doing its best not to drain the handset
battery. One the cell site end, it's no better as the power
consumption of a typical cell site is non-trivial.

Problems? Well:
<http://www.roughlydrafted.com/2008/08/28/the-inside-deets-on-iphone-202-and-dropped-calls
/>
Hmmm... power control algorithm again.

Todays typical cell phones run about 150mw max average power output
(according to the FCC ID data). Some are even less. None are
anywhere near the 600mw legal maximum. If they could, you would have
a dead battery within about an hour. (Do the math).

Back to wi-fi and your setup. Sure, you'll have fairly good
preformance with a high power setup. 14 times the usual power is
bound to do some good. However, I suspect your neighbors are not so
thrilled and will probably also be shopping for higher power hardware.
It will be like an arms race, where the biggest bomb allegedly wins.
Dealing with mutual interference is no fun, especially with only 3
available non-overlapping channels.

About a year ago, I was trying to find the source of a very strong
2.4GHz signal in the downtown Santa Cruz mall area. Wi-Fi
communications among the various coffee shops and hot spots was
ummm.... a challenge. I eventually traced it down to a tall
residential hotel and a 2.4GHz cordless digital phone running what I
guess was a 10 watt power amplifier. Instead of a cell phone, this
person decided to provide his own cordless phone service that covered
the entire downtown area. You could see it anywhere but as is
predictable, his useful range was limited by the handset power, which
was well less than 10 watts. I'm not going to go into detail on
exactly what happened, but it should be sufficient that he's now aware
of the problem he was causing and is off the air.

Be the first in your neighborhood to dominate the airwaves:
<http://www.ssbusa.com/kunamp1.html>
Cool... 50 watt linear on 2.4GHz. Now, we're cooking.

>This same issue is significant in other bands, as well. My area's

>a coordinated repeater's transmit coverage and receive coverage should
>be consistent. Having an ultra-high-powered transmitter simply causes
>interference well outside the repeater's practical use range.

Good plan but there are problems. Most hams these daze use walkie
talkies with perhaps 1 watt of TX RF. The typical repeater is running
perhaps 10 to 40 watts out (after the duplexer). The walkie can hear
the repeater almost anywhere, but when trying to talk, they drop in
and out all the time. The mobiles, which run more power, are usually
well matched to the repeater's tx power. I've suggested adaptive tx
power control (to preserve battery power) on our 2 meter repeater, but
nobody wants it.

>Having overly-sensitive receivers can also be a problem, albeit a
>lesser one, as it means that the repeater can be "keyed up" by remote

>a problem, though, as most repeaters use CTCSS tone squelch these days
>and won't respond to signals intended for co-channel repeaters with a

>different CTCSS tone.

We had a co-channel user that was running carrier squelch. It took only about 7 years of constantly pounding on the trustees before they would install PL. They lied on their NARCC application claiming they had a functional PL system. The experience taught me a few things, one of which is that hams generally make lousy RF neighbors.

>I don't think this is an issue for 802.11
>access points at all.

No, it's not for most home systems. There's a similar coexistence problem with mesh networks and municipal networks. Neither of these scale very well. They work ok with a small number of repeaters, but rapidly foul up as the usage, traffic, and number of repeaters increases to the point of mutual interference. Details and a rant on request.

There's also a problem with wi-fi and omnidirectional antennas. These pickup and spew inference from all direction equally well. Same with reflections and multi-path. If the main area of operation can better be covered with a directional antenna, then it should be used. It may create hidden nodes, but those can be handled by enabling flow control.

> - 73 de Mike N3LI -

Mike,
I see no end to the present trend. A few decades ago GE here in
Bloomington started moving its manufacturing products overseas
only later to sell as they moved away from manufacturing and into cash
handling businesses such as banking, tv and the like..
Bloomington had a couple of plants making vacuum cleaners, they
moved out to Mexico. Beich's candy was sold to a Swiss company
Also had a major switch yard on the railroad which is now a waste
land.Result We paid for Mitsubishi to settle here to make cars.
Insurance companies got bigger here churning money and now import
Indian software people as they state american programmers do niot come
up to
par. The city commerce department encouraged hotels to be built
together with the import of 10K mexican workerst6o keep them clean and
hospitals became larger as immigrant births ballooned as insurance

against deportation which then increased taxes for bilingual
education.
All this because we moved away from letting the existing market
decide as we went global knowing that american ingenuity was the
answer to all.
Now Universities are getting failing grades thro out the country where
their products were intended to be the savior of capatalism which has
now changed
as entrepreneurs changed the "market" instead of strengthening the
infro structure. Now the motor industry wants feed money to continue
to build cars
with high labor content that cannot compete. So the idea of let the
"market" decide has now also disapeared as we nationalise/take over
our industries.
Americas answer? Pull away from the dissemination of science and try
to remold the World (market) to match our needs. Suppression of the
meagre results in universities is such a small dent in the overall
picture. But all knew what the total end effect would be. History
shows that all that seek an empire
always over estimate their abilities to retain what their military had
won such that another new empire emerges.To increase market size while
decreasing
population wealth eventually only leads to total domination or
widespead civil strife.
Greed is a terrible thing
Pull up the ladder Jack. To heck with the others i'm O.K. and that's
the most important thing for today. Tomorrow is another day

For real. We continue to do this to ourselves.
Check this out:
http://www.youtube.com/watch?v=QVkjCQCTOEI

I'm not saying he's right, or that we should MAKE him right, only that this
is the perspective of someone who somehow has an interest in looking into
it.

<JIMMIEDEE123@YAHOO.COM> wrote:

>Tim, I solder these on the N connectors all the time with no problems.

In past life, in a land far far away (Smog Angeles), I once worked for and later ran a comm shop. At the time, UG-21/U male N connectors were commonly available and in fashion. Our 460MHz repeater systems were full of them so I had plenty of experience in soldering, assembling, and repairing these connectors. I don't want to remember all the 25 mile joy rides up the fire road to Santiago and Mojeska Pk just to fix a problem caused by a flakey UG-21/U coax connector. Well, to be totally accurate, I had equal problems with soldered PL-259 connectors. I fought these problems for years because I assumed there was no better way.

Meanwhile, I was also involved in an avionics shop (on the business end). They were slowly switching from soldered to crimp type connectors. The owner insisted that is was worth the effort because the number of connector failures and rework had approached zero with the crimp type. I became a believer overnight.

Many years later, I designed a few marine radios for the USCG. The specs would tolerate either solder or crimp. So, I asked which they preferred. Crimp was the answer, because they never could teach the techs how to properly solder a connector, while the crimper always does it right. All our radios used crimp connectors, even on the inside.

Roll forward more years and we have 10Base2 and 10baseT ethernet. The former uses UG-21/u N connectors. The latter uses BNC. The nice yellow coax cable with the flakey connector was a constant source of headaches. The crimp type BNC's never failed (unless abused).

I'm not sure what to suggest. With skill UG-21/u can be made to work. With luck, they can even be kept working in the field. However, I'll take crimp type any day, especially after many year of experience dealing with both.

I just tried Firefox, I see what you mean. The advantage of using the .mht file is that I have everything wrapped into one file. If I lose my copy I can recover by simply download the file from the web site and us it to update. I am using Word 2007 (only use it if you have to, I receive .docx files for newsletters!) and it is pretty easy to put together a web page while thinking of other things. I have trouble keeping things sorted out with more than one site in a web space. One file for each subject works well for me.

The real clinker for an .mht one page in one file is that the source is all included in the page which requires the user to download a lot of stuff that is disregarded.

I will work on getting back to the mainstream.

Thanks for the heads up...

Seems to me that would introduce another set of incompatibilities.
People out on the fringe area of the repeater's coverage would be able
to hear repeated signals from weak transmitters (e.g. HTs), but if the
repeater saw a strong input signal from a mobile (or an HT near the
site) and dropped its transmitter power, the repeater coverage area
would shrink abruptly and those users out around the edges could lose
coverage. This could re-create the "hidden node" problem in a new way!

I don't think adaptive power management can work reliably in the
absense of a signal-quality feedback from each station which is
accessing the repeater/AP.

Grrr. <Worf> "Romulans have *no* sense of honor." </Worf>

Our system (W6ASH, SPECS, at El Camino Hospital in Mountain View)
switched over to PL-tone-only years ago, and it helps in numerous
ways... the absence of noise-initiated kerchunking is a real blessing.
I've preserved the ability to switch the repeaters over to
carrier-sense-only in an emergency but really don't expect to ever
need to use this feature.

> The experience taught me a few things,
>one of which is that hams generally make lousy RF neighbors.

Some are lousy neighbors, lazy and self-centered. Others hold
themselves and their equipment and operation to very high standards. I
think it depends very much on the individuals involved, on their
attitudes, and on their level of prior experience in supporting a
real-world user community.

I believe you!

My impression is that a limited set of mesh repeaters, and a plentiful
set of direct backhaul links on a different (non-interfering) band,
works out rather better.

Yes, hackers (well, you may prefer programmers/software-engineers?) do a
very nice job, they have done it with wifi too, still doing it actually,
personally--I suspect viagra! LOL

Yeah, personally, I could handle a cell phone 2x to 3x the size, most of
it battery ... my cellphone is 300mw out (max, but variable, as needed,
as you state), I read those specs before purchasing, also. 4 hours max
talk time (like if your sitting right under the tower?) is no problem
for me, mine averages 2-3hrs, but I have a pocket charger, takes two AA
high output recharge-ables (you can chuck alkaline in if needed) and is
quick, chat while charging, so never without power (did I mention 2 week
standby time?), now ask the wife, you get another answer ...

> Back to wi-fi and your setup. Sure, you'll have fairly good

> Dealing with mutual interference is no fun, especially with only 3
> available non-overlapping channels.
>

My son and I, once or twice a year, attend a game fest. There is more high power equip set up than you can shake a whatever at ... doom, heretic, diablo, etc. (you can tell, I like the old ones :-( ) nets all off separate APs, the wifi cards are simply uncountable--if you think thats nuts, attend a gaming convention in Nevada, frankly, I would have to state, from REAL hands-on, the problems you state just don't exist to a REAL degree ... if they/it did, they would be fixing that now (more chans, tighter packet packing/encryption, more-adaptable, spread spectrum, etc. Remember, networking has NOT EVEN reached its' infancy, yet!) Without a doubt, there are conflicts and lost packets--you just never notice them--now, if everyone there started, separately, watching a HD movie, most-likely no joy ... :-(

Besides, my neighbors are idiots (technical idiots, I admit, I like a couple of 'em), I doubt they do anything but email/surf and download an illegal movie/song now-and-then -- well, I suspect them of porn--but I am like that yanno? Suspicious.

But hey, if everyone agreed with me, I would NOT be here, and this would NOT be fun--did I mention it would be boring? <wink>

Warm regards,
JS

All the problems you state would disappear with the correct algorithms
controlling the packets/encryption/compaction ... there is just not
enough interest to put together a team together to do it, and a
for-profit organization would go broke doing it ... and, you can't get
everyone to agree. The (A)ncient (R)etarded (R)adio (L)aggards) don't
see a need--you see, no brass is required ... :-(

Actually, the technical aspects and military-ization of our police has changed the terrain. Now you need the equiv or road-side-bombs used in Iraq, flame throwers to burn them in their Kevlar, armor piercing ammunition, small surface to surface missiles, etc. ... not impossible, just more difficult.

We now need a civilian group to oversee the president/government--perhaps one which is militia based would be appropriate. It certainly is time this surfaces to the realm of rational discussion ... they are no longer OUR servants! We simply have to get their attention and focus back ...

Good point, but that's not what I had in mind. I was aware of the
problem and suggested that the power control be run by a micro. The
algorithm needs to be worked out, but basically, the weakest signal
sets the power level. The range of power adjustment also will not be
huge or large enough to have much of an effect on distant stations.
Our current 60 watt amplifier might have the power output reduced to
about 20 watts or 4.5dB power reduction. That's less than one S-unit
and probably wouldn't be noticeable even by distant stations. However,
it will make a huge difference in power consumption and battery
operation run time. There are a few other economies that can be
thrown in, such as having the repeater always ID in low power. Of
course, there are complications, such as the mobiles and handhelds not
reporting their RX signal quality, which makes deciding the repeater
power output somewhat problematic when dealing with the traditional
broken radios. (Same people, same radios, same problems, same club
net, every time). Incidentally, this was suppose to be a minor
feature of a proposed repeater voting system, which is another can of
worms.

>I don't think adaptive power management can work reliably in the
>absense of a signal-quality feedback from each station which is

>accessing the repeater/AP.

Yes it can. I intentionally reduced the repeater TX power during a club net from 60 watts (before the duplexer) to about 20 watts. Nobody said anything, there were no complaints, and nobody noticed, even after I mentioned it after the close of the net. As long as I don't run the power output to near zero, it can me made to work, even if the power level is set manually with a touch tone command.

>>We had a co-channel user that was running carrier squelch. It took

>>had a functional PL system.
>
>Grrr. <Worf> "Romulans have *no* sense of honor." </Worf>

Actually, it was far more stupid than it appears. We had several of the club politicians pounding on the alleged trustee of the repeater, who literally didn't care, didn't communicate with the rest of the organization, broke numerous promises to take it up with the board, and so on. Complaints to NARCC went to the trustee with predictable results. We were simply talking to the wrong person. One day, we caught the right person on the air working on the repeater. He was informed of the situation, after a few emails and the usual miscommunications, the PL decoder magically appeared. As would be expected, the initial transistion was slow. First there was no-PL during their club nets. Later, it became full time. There was also some work done on placing a notch in the antenna pattern in the direction of Santa Cruz. That has worked quite nicely.

>Our system (W6ASH, SPECS, at El Camino Hospital in Mountain View)
>switched over to PL-tone-only years ago, and it helps in numerous
>ways... the absence of noise-initiated kerchunking is a real blessing.
>I've preserved the ability to switch the repeaters over to
>carrier-sense-only in an emergency but really don't expect to ever
>need to use this feature.

That alleged benefit is that no PL allows visitors and hams with antique hardware to use the repeater. We have a control code that is available to anyone that will temporarily disable the PL for a specified time period. It actually does get used by some hams who apparently plan on being buried with their ancient radios and have no intention of ever selling them.

>> The experience taught me a few things,

>real-world user community.

It varies. I consider myself a good example of one of the lousy RF neighbors, so I know they exist.

>My impression is that a limited set of mesh repeaters, and a plentiful
>set of direct backhaul links on a different (non-interfering) band,
>works out rather better.

Sure, but that's not the way most municipal wireless networks are umm.... engineered. Most are single channel, store and forward repeaters. The problem is that if you're perhaps 3 nodes away from where it hits the wired internet, you will have 4 identical duplicated packets flying through the air. If everyone can see everyone else (as is the case with omni antennas on office rooftops), only one of those radios can be transmitting at a time. That means that you would be hogging at least 3 times the shared bandwidth (airtime is shared) to deliver one lousy packet. Add the problem of trying to create the ultimate geographic routing algorithm, and mesh networks have a propensity to fill the airtime with duplicates, retransmissions, and junk. The worst of the worst are broadcasts, noteably ARP requests, which go everywhere. I was monitoring what was coming out of Google's Mtn View network and finding about 60% of the airtime occupied by ARP requests. Of course, when the proponents of municipal wireless find that there are holes in their coverage, they just add yet another store and forward mesh repeater. Eventually, the density is high enough for the mesh repeaters to start interfering with each other. Since this is difficult to diagnose, the usual solution is to increase the TX power of the mesh node. That does the opposite of what might be expected, but until the numbers are in for availability testing, everyone just assumes that more power is more better. It took quite a bit of arguing to convince one mesh operator to reduce their power and even more to demonstrate that it worked. As an example, see the data and conclusions from the old MIT RoofNet at:
<http://pdos.csail.mit.edu/roofnet/doku.php?id=interesting>
Note the probabilies of actually delivering a packet through just one hop. Yech.

I couldn't resist and just had to rant. But, it was worth it.

Onward to another thrilling day of doing battle with QuickBooks and my traditional end of the year billing nightmare...

I suppose in the cities you have different views of the police but
without money
they then become part of the public, good or otherwise as in New
Orleans,
On the other hand gun sales are sky rocketing in the Midwest so one
can shoot deer I suppose
and I can't see Obama saying "let the public eat cake". On the other
side of the coin, if the public is
not paid enough to buy the products that they make it becomes a
question of living or dying, your choice!
Do you think that hams will come to the aid of the government in a
case of crisis?
I think we should let this thread die before we are accused of
sedition
Regards
Art

Would it? A lot of amplifiers don't change their power consumption all
that much, especially if they're designed for saturated operation (i.e.
if you reduce the input drive, they either distort, or drop into linear
mode and dissipation goes up).

if you have an amplifier designed for variable power output, then what
you say might be a good idea.

[snip]

Yep, I thought as much...

[snip]
> Peter's spinning antenna wouldn't produce a circularly polarized wave (as
> universally defined) even if it was synchronous with the wave frequency.
> As I've said, a circularly polarized wave has constant E field amplitude;
> Peter's wave would have a time-varying amplitude. If it were synchronous,
> the nulls and peaks would always occur at the same places in the rotation
> cycle, so they would occur at fixed angles relative to a rotational
> reference point. If non-synchronous, the nulls and peaks would rotate at
> the beat frequency.
[snip]

The problem is... that most "conventional" code and theory, e.g. NEC
does not allow for antennas in motion. These theories and computer
codes/algorithms are based upon a static steady state solution of the
Maxwell/Heaviside equations... i.e. E is a "fixed" phasor rather than
an oscilating waveform.

[snip]
> It seems to me that the way to mechanically generate a circularly
> polarized wave would be to rotate a source of *static* E field, for
> example, a short dipole with constant applied DC voltage at the feedpoint.
[snip]

Hmmm... restricting that dipole to a "static" source is really far too
restrictive. This assumption likely results from the assumption
that E is a sinusoidal steady state value rather than a dynamic
(transient) wave.

[snip]
> That should produce a circularly polarized wave with the frequency being
> the rotational frequency of the dipole. At any point in space, the E field
> would change with time, and would propagate, and it would look exactly
> like a circularly polarized wave broadside to the rotation plane.
[snip]

Yes, but E is not "fixed" in time, it is the magnitude of an oscillating
phasor!

A DC phasor would not propagate. Of course!

[snip]
> If the scheme works and radiation is occurring, then power must be going

> the field from its previous position, which induces a current in it. Hence
> the current. It's fundamentally a generator, with the field being in the
> air.
[snip]

Yes that would be the case if the rotating antenna was excited with DC,
however that is not necessarily the general case.

In general the "center" frequency or "carrier" frequency may be any
arbitrary frequency, down to and including DC. Maxwell's/Heaviside's
equations hold for all frequencies from zero (DC) to infinity.

[snip]

[snip]

Wow! Roy.... you are taking a big risk here. What is the (exact) value of
that
"sum"?

[snip]

[snip]

Jerry... no one on this thread, except perhaps Roy, has restricted the
"frequency" of
the signal applied to said mechanically rotating dipole to be zero, f = 0!!
In fact, in principle,
the frequency of the signal applied to the rotating dipole could be any
desired frequency
selected from the frequency range minus infiinty to plus infinity.

>
> Jerry KD6JDJ
[snip]

There are many practical examples extant of such "rotating" fields...

Consider the rotating field generated within the stator of a "shaded pole"
electric motor, or perhaps
the roing field of a synchronous electric motor.

However the rotating electromagntic fields of AC electric motors have
conventionally been
synchronized with the frequency (60Hz in North America) of the exciting
waveform. That
commercial application does not preclude applications wherein the rotating
field of an AC
motor is not synchronous with the exciting prime mover. For example,
imagine a motor
wherein the stator magnets are rotated by a separate mechanical device,
bicycle pedals?,
that pulls the rotor around at a frequency not synchronized with the stator
prime mover
excitation. Just because there is no real commerciall application for such
a motor in
today's markets, does not mean that such is not useful for some other
purpose.

Open minds create new applications

[snip]

Roy has got you guys hung up on DC!!!

What is all the magic in DC. DC is just one of a double infinity of
frequency values that
could be applied to a spinning antenna!

This direction of investigation is similar to Cecil Moore's assertion that
there are no
reflections at DC.

There is nothing special about DC, it's just another of the infinity of
excitation
frequencies available.

Hey! Maxwell's/Heaviside's equations do not restrict excitations to any
specific
frequency.

There is no special status assigned to f = 0.0, get over it!

How about f = 0.0000003333 Hz, instead of DC, what then?

Weller manufactures the following of that type of solder guns:

8200 = 140/100W
D550 = 260/200W
D650 = 300/200W

See http://www.cooperhandtools.com/brands/weller/index.cfm

I have an 8200. They make plain copper and iron-clad copper tips (the iron-clad tips last longer). The beauty is that, when your only tip goes open and the local hardware store is closed and you HAVE TO solder something, 12ga solid copper wire can be formed into a tip. :)

[snip]

Apparently nothing!

Jerry it seems that I have an older version of EZNEC, a version that did not
support CP outputs.

I just contacted Roy todayh and ordered the latest upgrade to EZNEC +
version 5 which
Roy tells me supports CP outputs.

But... one thing about NEC is that it does not support antennas in motion.
NEC and all of the commercial
software that is derived from this (US Taxpayer supported code, God Bless
the US Taxpayer!) do not
support antennas in motion. Rather NEC supports only static antennas in
steady state excitation.

There may be some "multi-physics" programs/software out there that can
calculate radiated fields
for antennas in motion, but I am not aware of them. Of course I'm not an
expert and I have not done any
research on this topic and so I don't personally know of any programs that
can produce
CP outputs for antennas that are in motion, specifically symmetric antennas
that are rotating
at some arbitrary angular rotation velocity with respect to their axis of
symmetry.

BTW... Do you happen to know of any programs/software that can
simulate/emulate antennas in motion?

Just asking...

I still have a dual power (500/250) model Weller gun that a friend bought while we were in the Air Force. He took it out of the package and dropped it on the floor accidentially. A tiny piece of non functional plastic busted off the top, so he threw it in the trash can (he was having a bad day). I pulled it out of the trash, plugged it in and showed him that it still worked fine. I then offered it back to him. He wanted no parts of it. I'm still using it to this day. That 500 watt heating range actually comes in handy now and then.

I suppose in the cities you have different views of the police but
without money
they then become part of the public, good or otherwise as in New
Orleans,
On the other hand gun sales are sky rocketing in the Midwest so one
can shoot deer I suppose
and I can't see Obama saying "let the public eat cake". On the other
side of the coin, if the public is
not paid enough to buy the products that they make it becomes a
question of living or dying, your choice!
Do you think that hams will come to the aid of the government in a
case of crisis?
I think we should let this thread die before we are accused of
sedition
Regards
Art

Toilet bombs are more surgical. Catch em where they go.

Isn't sedition what we do to get ready for an election?
But then you and I don't have the Millions and Billions
to overthrow the Government with, so at best we are just
nuisance.

Actually the cops might sooner or later realize they are just
an army dangling off the end of a phone line ready to roll for
the biggest liar and might just be doing someone else's dirty
work. What's most worrisome is the ones that decide who
gets the Gov. jobs or the media jobs in the first place.

That's where we have been underestimating the enemy.
If some people want to get together to take over something,
they can pretty much do it all over people who are trying to
be fair about things.

Violent revolutions don't happen without lots of people
running around with nothing better to do, but technology
has a way of putting people way out of reach of such
unpleasantness. This is probably the biggest reason
things never progressed to a violent revolution like China
or Vietnam and capitalism never lost it's place. A well
disciplined military probably has lots to do with that too.

Obama has been saying "let them eat cake" for a long
time. I wonder if anyone caught his Dec 2 governors
meeting on the economy where he tells them "...change
is going to come from YOU, not from Washington". I was
hoping he would at least be willing to learn but the voters
have a lot to learn for sure.

It is not an arithmetic problem and I have "put to bed" transcription
or math error. I am designing a multiple technology network. The only
one causing me problems is Zigbee. Where do you get this from:

> This is your confusion factor, and it relates to transcription error
> in the abstract: you are using the wrong formulas entirely regardless
> of the accuracy or correctness of arithmetic results.

I've talked to experts who have supported my claims. Unless you can provide me with more than just random conclusions, I may be able to get to the bottom of this. Otherwise, your posts have been much less than helpful.

You are right, if all goes well, we stop paying the crooks and they go home ... however ... if not ...

You will need the guns, IF the government has reason to hunt you, you will need the guns for food (you may have to learn to eat government officials!)--while you live off the land ... they are good, the guns.

But, doing a "Clint Eastwood" on a swat squad? Hmmm, show me?

However, knowing how to make explosives out of obtainable materials may make a person a "technical expert", indeed, it may make one a valid guru--something I have NOT seen in ages! Knowing that perchlorates exist in common bleach and how to use them as oxidizers, this is good! Knowing how to construct a flame thrower out of an air tank off a semi-truck, some tubing, a valve and bicycle pump, and able to use any fuel may just make one a desirable friend ... ya never know, ya just never know ... your best ally? An open mind!

One question which is always valid, "Are we men, or are we mice?" (Or, are we sheep, or are we free?) My father was a man (actually, a free man--and a Freemason) ... you will have to watch me and make up your own mind--as to myself ... :-)

But then, how do you know I am not just kidding? <evil-malicious grin>

When we see American Terrorists, we WILL know change is in the wind, let it be a good change ... and let them kick those whoosie mooselims butts!

Regards,
JS

If multipath and interference fall into the category of random
conclusions.... You were wrapped around that axle more than two
years ago.

The search term of Zigbee and Ginu (enlarged to include your alias of
Omar Fink) fairly draws a portrait of someone wandering through a fog
of 3000 threads and postings. I can see why this has mystified you
for five solid months - you are out of your element.

You've been given every extrapolatable answer from across several
dozen outlets. As I suspected earlier, the simplest answer is that
Zigbee isn't designed to do what you expect of it. Roaming the planet
asking the same question is unlikely to provide any different outcome.

You seem to be missing the noise figure of the receiver in the calculation,
and making assumptions about the receiver noise bandwidth that may not be
correct.

If you know the rx sensitivity is -94dBm at the data rate you require, why go through all of the Shannon stuff, it is not revenant. You have been told that the Rx sensitivity is -94dBm use that figure.

> sense?

Perhaps because most quoted ranges for Zigbee are in the order of 50m not 500m????

So you have an rx sensitivity of -94dBm and a path loss of 94dB, so with a tx power of 0dBm you have a receiver operating at its sensitivity limit. So you will have a link with a Bit Error Rate of whatever the manufacturer quoted the -94dBm sensitivity figure at (10% BER?????).

> However, 1mW happens to be the maximum transmit power of Zigbee of
> roughly 0 dBm,

Exactly 0dBm actually

> Testing other distances, say 300m, we get a maximum transmit power Pt

> -4.41 dBm = 3.6211e-004, which is > our maximum transmit power Pt.

How is -4.41dBm greater than 0dBm (1mW) ?? It is about 0.362mW.

Your maths is quite simple; you have the rx sensitivity, and can work out the path loss, thats all you need to do, take one from the other and you have the required tx power.

Of course your formula only gives the free space path loss, reality is likely to be considerably worse!!!

I dont have a problem with crimp on terminals just that where I work someone has always borrowed the crimp tool just when I need it. I always have my trusty soldeing gun handy, no one wants to borrow it. For me one is as easy and works as well as the other. The biggest problem I have with the non crimp type is the shield is eventually cut from the connector. The ones at work that are disconnected weekly for preventive maintenance have only lasted about 20 years before needing the connectors replaced, BUMMER. The crimp-on type are not without their problems. I was doing an inspection after some equipment installation and was able to pull the the ends off of 20 BNC connectors. The inspection stopped at that point and the decision was made to reaccomplish all of the connectors, about 200 of them. The installer was not happy. The problem turned out to be a bad crimp tool. Like the solder-ons if done properly they are both reliable connections.

DC is just AC with a very low frequency. After all you have to turn it
on some time and some day it will turn off.

"- 96 db seems about right for "free space" path loss."

96 seems abour the right number for a path loss at 2400 MHz at a distance of 500 meters. To nit pick, -96 db loss is a gain.

I worked a few years with Pete Saveskie who wrote a book he called "Propagation". It contains a formula for free space loss: 23 db is lost in the first wavelength from the transmitter and after that 6 db loss is added every time the distance is doubled.

With Pete`s formula, you would lose the 23 db at a distance of 0.125 meter, and at a distance of 512 meters you would lose a total of 95 db. That`s close enough agreement for me.

Best regards, Richard Harrison, KB5WZI

Typical red herring argument. When you don't have a answer, then proceed to insults and character assassination. Gee, wasn't Obama from Al Capones neck of the woods? I mean how do you beat up people for votes if you don't have their unions and livelihood in the palm of your hand. Oh! that's right, Obama's not a crook, he's a LAWYER! His favorite idol is Saul Alinsky (who seems to be the hero of the party since so many quote him) who actually worked for Al Capone! Then there's his "spiritual advisor" that he had to distance himself after 20 years of EXPLOITATION of race and class divisions.

Republicans keep harping about conservative "values" like personal responsibility and not killing babies for the sake of convenience. Democrats think of the little people as votes and "manure for the revolution" and that its stupid to go down with your team when you can just "throw someone under the bus" (the vernacular of ACORN).

The only difference I see is one that is shamed into following their own rules and another who simply changes the rules or the judges.

I know the problem. Tools are expensive. However, there are a
variety of cheap replacements that seem to work well for me:
<http://802.11junk.com/jeffl/antennas/Misc/slides/crimpers.html>
I have several sets of these that cover everything from RG-188 to
LMR-400 size coax. There's also one for LMR-600 but it was being
borrowed when I took the photo. (Yes, it came back eventually). I
think I paid about $35/ea for the tools in the photo. At that price,
spares are an option.

>I
>always have my trusty soldeing gun handy, no one wants to borrow it.

When I was working on the bench, I had my soldering iron bolted to a
large block of wood to discourage the borrowers. My biggest problem
was someone trading or outright stealing my Weller solder tips. I
kept my supply locked up and hidden.

>For me one is as easy and works as well as the other.

I beg to differ. Many of my connector installs had to be done in the
field, usually at a mountain top repeater site or up on a tower. The
problem was that the wind would cool just about any soldering iron,
gun, or even a propane torch, sufficiently to cause problems. Same
with the USCG vessels, where the coax was snaked through the mast, and
the connector had to be crimped at the top in the field. The only
place where I would effectively solder a connector was inside a
building. I do recall one day on a tower, when I draped my jacket
over my head, and soldered some connector by flashlight, but I don't
recommend doing that.

>The biggest
>problem I have with the non crimp type is the shield is eventually
>cut from the connector.

Agreed. I have the problem with my test cables. A good strain relief
is a big help at immobilizing the shield. Pomona jumper cables have
molded plastic strain relief's. I use clear shrink tube (so I can see
when things are starting to come apart). In general, it's nut much of
a problem as I have far more UG-88/u BNC plugs fall apart than the
crimped variety.

>The ones at work that are disconnected weekly
>for preventive maintenance have only lasted about 20 years before
>needing the connectors replaced, BUMMER.

Weekly? 52 weeks per year times 20 years is over 1000 connector cycles. That's quite a few. I suspect the ears on the BNC jacks will also be worn. I'm not surprised that they're failing. I did some Googling and found specs for UG-88/u connectors ranging from 500-1000 mating cycles. Methinks you're at the upper limit of the lifetime.

>The crimp-on type are not
>without their problems. I was doing an inspection after some equipment

>connections.

Bummer. At one employer, we had an Amp-o-lectric crimping machine. Someone found that it was possible to mis-adjust the tool to produce defective crimps and proceeded to explore the possibilities. I was blessed with dozens of field failures and a recall because nobody had thought to run a pull test on the crimped connections. Everyone assumed the machine could do no wrong. However, that's the big advantage of a crimped connection... it's consistent. I can't get that kind of consistency from soldered connectors, especially those done in the field.

Incidentally, I've seen more damage done by the razor blade coax stripping tools, than by the crimping or soldering. One nick in a solid center conductor and the center pin connection falls apart inside the connector. I try to use a thermal wire stripper, but that also takes some skill.

Also, a lot of published descriptions of various communications schemes (e.g. Zigbee, 802.16e) might give a maximum data rate and a maximum range, but that doesn't mean you get both at the same time. The former is often related to the system bandwidth, the latter to the minimum data rate and transmitter power.

I think you can get a ballpark feel pretty quick.. use the free space path loss (in whatever form you like). Calculate required receiver power as
-174 dBm + 10log(datarate in bps)+ 3 + receiver NF. (use 2dB for NF if you like)

Add path loss to required receiver power, and that's what you'll need for EIRP from the transmitter.

Yes, assumes isotropes, and ignores coding gains, etc. But you'll be within 10dB or so, and that's enough to know if you're even in the ballpark.

If you do the calculations and you come up with a required transmit power of +50dBm (100W), and you're thinking small battery powered, you know it ain't gonna work. If you come up with +10dBm, and battery powered is the goal, you're in the ballpark, and THEN you can start thrashing through the more detailed modeling.

And, why would this be "important"... it doesn't support arbitrary
terrain surfaces either, nor non-uniform soil properties.

Since the vast majority of "amateur radio" antennas (this is r.r.a.a,
after all) can be modeled adequately by NEC.

If you need more, fork out the bucks for a FEM code that does what you need.

As you say, you've not researched it.

I would suggest that the need for such a thing is fairly small, but I'll bet someone somewhere has done it, just not as a "end user" software product.

Certainly, there IS a lot of modeling of EM waves from moving objects (radar reflections being of particular interest).

Depends on the relative scales, too. If you're talking waves from a meter scale object viewed from kilometers away, then using a point source approximation for the object will work nicely, and then it's just simple geometry.

For FM repeater use, the amplifiers are usually Class C or overdriven
Class AB. The output devices are alternately driven into saturation
and cutoff. I have some measurements somewhere for our various
repeaters buried somewhere. As I vaguely recall, the overall system
efficiency was about 50% for VHF and about 35% for the UHF repeater.
Of course, everything is properly logged and documented:
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/slides/Documentation.html>

There are a variety of methods of reducing power, but for Class C, the
easiest is to reduce the collector or drain voltage on the RF output
stages. This works well down to about 20% of rated output power, but
often causes nasty oscillations and parasitics. It also burns quite a
bit of power in the linear voltage regulator. Not ideal, but I know
it works from experience designing marine VHF radios, which were
adjustable and stable from 10-25 watts RF out.

My guess(tm) is that the VHF rack burns about 10A in transmit at
13.6VDC. The UHF box burns about 15A in transmit. The idea is to
reduce this to the absolute minimum, and still have a usable machine.
Ideally, the power control should be automatic.

You're correct that the efficiency drops badly at lower power, but
reducing the overall current consumption is the goal here. The
efficiency may be lousy at low power, but if the overall current

consumption drops proportionately, it's good enough. The idea is to
be able to run the repeater for several days, in an emergency, on
battery power:
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/slides/Batteries.html>
I might setup a switching regulator to reduce the power dissipated in
the voltage regulator circuit. I've never tried this but it seems
easy enough. Power amp distortion is not an issue here as the FM
repeater doesn't have any linear components in the RF signal.

The K6BJ repeater:
<http://www.k6bj.org>
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/index.html
<http://www.LearnByDestroying.com/k6bj/IRLP/index.html>

>if you have an amplifier designed for variable power output, then what
>you say might be a good idea.

Nope. None of the amps are designed to be operated that way. Few
commerical FM transmitters and power amps are designed for adjustable
power. Such details have never stopped me in the past. However, club
politics, other priorities, and my health issues have slowed me down,
thus nothing has been done.

Art wrote:
"When Maxwell inserted the required units to acheive equilibrium per Newton it was the mathematics that forcast the presence of a levitation force that would not be identified for several decades but still ignored because of the dominance of wave theory."

Maxwell found his equations had the form of those predicting behavior of water waves and they correctly predicted the velocity of light as previously determined.

Maxwell was a mathematician and a physicist who searched for things with practical applications. In one of Maxwell`s lectures he said: "Now, Professor Graham Bell, the inventor of the telephone, is not an electrician who found out how to make a tin plate speak, but a speaker, who to gain his private ends, has become an electrician."

Maxwell`s equations are adequate to solve all questions of radio waves at once in place of a multitude of their predecessors. Art even agrees they work as a basis for antenna programs in computers however he spells computer. Using the tried and proven until something better comes along is common sense.

From what i`ve seen, wave theory works well for large scale predictions while the particle theory seems to work at the atomic scale. Too bad Cern had an instantaneous multimillion dollar breakdown.

A.G. Bell produced the most valuable patent in history. What are the results of the Unwin patents?

Best regards, Richard Harrison, KB5WZI

Thanks Jeff for your reply. Below are my comments:

> You seem to be missing the noise figure of the receiver in the calculation,
> and making assumptions about the receiver noise bandwidth that may not be
> correct.

The overall receiver noise figure is included in the receiver
sensitivity, is it not? I'm referring to http://www.edn.com/article/CA6442439.html
where they state that:

"the receiver sensitivity S=−174 dBm/Hz+NF+10logB+SNRMIN, where −174
dBm/Hz is the thermal noise floor, NF is the overall-receiver-noise
figure in decibels, B is the overall receiver bandwidth, and SNRMIN is
the minimum SNR. If the total path loss between the transmitter and
the intended receiver is greater than the link budget, loss of data
ensues, and communications cannot take place. Therefore, it’s
important for designers developing end systems to accurately
characterize the path loss and compare it with the link budget to
obtain initial estimations of the range."

Do you have any comments on this?

> If you know the rx sensitivity is -94dBm at the data rate you require, why
> go through all of the Shannon stuff, it is not revenant. You have been told
> that the Rx sensitivity is -94dBm use that figure.

That requires a long-winded answer about my project. My study involves
optimizing a multiple technology network where each device is
optimizing their transmission. Using the Shannon theorem allows me to
perform this optimization of data rate while considering physical
layer constraints. It's something I have to work into it
unfortunately. It's functioning correctly for WiMax and ultrawideband
technology.

> > -94 dBm = P_required + G(2.4E9, 500)
>
> > P_required is then easily calculated as -94 dBm - G(2.4E9, 500) =

> > kbps, which is the maximum data rate for Zigbee. So how does this make
> > sense?
>
> Perhaps because most quoted ranges for Zigbee are in the order of 50m not
> 500m????

The approximate line-of-sight range for Zigbee is 500m. That's why I
tested both 300m and 500m in my calculations.

> > Testing other distances, say 300m, we get a maximum transmit power Pt
> > = 5.9181e-007 = 0.59 uW to transmit at 250 kbps, but a P_required =
> > -4.41 dBm = 3.6211e-004, which is > our maximum transmit power Pt.
>
> How is -4.41dBm greater than 0dBm (1mW) ?? It is about 0.362mW.

I meant that, for my example using a distance of 300m, the transmit power required to transmit at the maximum data rate of 250 kbps was 0.59 uW. The required power to reach the MIRS at the receiver 300m away was 3.6211E-4. Therefore, the amount of power required to reach the receiver (a lower bound on power) was greater than the maximum power allowed to reach the max data rate of 250 kbps (upper bound on power). Therefore, the transmission isn't possible. It wasn't for 0 dBm.

> Your maths is quite simple; you have the rx sensitivity, and can work out
> the path loss, thats all you need to do, take one from the other and you
> have the required tx power.

That's exactly what I'm doing. The NF is included in the receiver sensitivity and the transmit power required to reach the receiver sensitivity is greater than the power I'm allowed to transmit at because of the 250 kbps maximum for the technology.

Thanks Jeff. I'd be interested in hearing your response.

Art wrote:
"So what exactly forces a time varying current to take an alternate route of travel from the center of the conductor when the resistance is so low compared to other routes that could be taken?"

Opposing ac current is total impedance, not just resistance.

The deepest fibers in a conductor are encircled by the largest number magnetic flux linkages. These create a reactance which generates a counter-emf opposing an imposed current. The deeper the depth inside a conductor, the greater the opposition to the imposed current.

Look for "skin effect" in any edition of Terman and you will find diagrams illustrating the various magnetic flux paths inside the conductor which cause skin effect.

Dear group,

As a temporarily solution I would like to use a cheap 5/8, 6/8 or 7/8 WL commercially available CB antenna as a non resonant vertical with elevated radials for use on 10 - 40 meters tuned by an automatic remote ATU at the base of the antenna. I used MMANA and EZNEC (demo) to calculate the expected impedance for the frequency range and found too many results for the height of the antenna. Now I am confused about what to select.
Is 5/8WL on 10meters a good height or 8 meter (22')?
What I want is a low take off angle on 20 and 30 meters with high efficiency and an impedance which my remote ATU can handle.

Such a tender ego, and pride of ownership is the first clue to its
easy bruising. As for trolling, your contributions have that distinct
"under the bridge" flavor. Put a notch on your keyboard and move to
the next group. Talk about wasting time.

Omar, it takes very little effort to review your trail to see you have
one foot nailed to the floor and the other on a skate. You haven't
altered your question much in 5 months (with every appearance of not
having progressed one jot), offered your heart felt thanks to all
those who "helped" you, giving you pretty much the same leads you said
you would follow up on....

And we find you at the next street corner with your hat out for more
spare change.

Hard to imagine how with so many similar responses that you haven't
gotten it yet, and more amazing you might think that the problem is
not in the question.

To a first order, you just want to avoid lengths where it's close to a
half wavelength (assuming you're using an ATU that's designed for this
sort of application) because that's where the Z is highest and toughest
to match. The low Z points are going to be easy (a few tens of ohms, and
almost any tuner can do that).

So, the lowest frequency where this is the case is where the wavelength
is 16m... straddling the 15 and 17m bands. In practice, what you might
need to do is adjust the length of the antenna by a few tens of cm one
way or the other to find a place where your tuner is happy.

Another situation is where the antenna is a full wavelength.. but 8m is
higher than the 10m ham band, so you're probably ok.

The other problem is if the reactive component gets too far for your
tuner to handle, but without knowing the tuning range of your tuner,
that's hard to know.

<you did good

are you just trying to learn the terminology or do you really
need to make some connectors and seek the best/easiest? way to
do that??

if you did you got a bunch of good tips here from the others

>
> Thanks.

i'll throw in a few other simular options to connectors

there are strip tools that can cleanly and safely strip the coax
they just spin around and do a great job i've seen cost between 50
to 100bucks depending on coax

also you can get a fixed center pin whereby you don't have to
solder or crimp, the captivated connectors the outer
sheild part gets a crimp only typically a bit of glue on the
inside heavy ga heat shrink shrink goes over all

they are rated very good soare are the center pins /outer shield
that gets crimped using the right tool of course

no matter what you use skills at doing the job and
inspection/testing of the work will always remain a constant

As in, the back of the envelope shows you've got 28 dB of positive
margin, or the uncertainty of your estimate is 28dB, or you're 28dB
under? It's inverse square law, after all, so 10 times the distance is

a 20dB change in power.

Zigbee is IEEE 802.15.4 at the PHY.. 250kbps at ranges of 10-100 meters for the 2.4 GHz band.

Let's see.. -174 + 3 + 54 + 2 = -114 dBm received signal level needed, bare minimum. Real receivers are probably more like -100 or -95. Chipcon's CC2420 is -94dBm

The 802.15.4 only requires a sensitivity of -85dBm

Zigbee transmitters are -3dBm transmit power (minimum).. typically, 0dBm might be more common.

So, let's look at a link budget for 10 meters
32.44 + 20log(2500)+20log(0.01) = 32.44+ 68 -40 -- about 60dB path loss between isotropes 10m apart at 2.5GHz.

-60dBm receive power vs -100dBm sensitivity.. So, it should work ok at 250kbps and 10m (assuming no interference, multipath, etc.)

Now, bump to 100m.. That's a 20dB hit.
500m another 14dB.. now you're on the ragged edge. 6dB margin with a -100dBm receiver and a 0dBm transmitter. And that's assuming isotropic antennas, which may or may not be reasonable.

My path loss results verify this too. The issue is this: if the range
is between 10-100 metres, how do we use a minimum of -3 dBm of
transmit power?

To transmit at 250 kbps on a 5 MHz bandwidth channel centered at 2.5
GHz to a receiver say 10 metres away, you only require 5.8009e-010
watts. That's the problem. This is the maximum power required. It is
far less than the -3 dBm quoted.

The 28 dBm that I stated was that my transmit power required to
transmit at 250 kbps is 28 dBm under the -4.4 dBm minimum transmit
power to reach 300m that I provided in my original post:

> Testing other distances, say 300m, we get a maximum transmit power Pt
> = 5.9181e-007 = 0.59 uW to transmit at 250 kbps, but a P_required =
> -4.41 dBm = 3.6211e-004, which is > our maximum transmit power Pt.

5.9181 mW corresponds to roughly -32 dBm, hence the 28 dBm under.

At the 10 metres that we are discussing here, the required transmit
power falls even further:
5.8E-10 watts = 5.8E-7 mW

This corresponds to 10*log10(5.8009e-7) = -62.365 dBm. So the margin
is actually 67 dBm.

The path loss model isn't the problem. And the Shannon capacity is known to be able to estimate any information channel.

This is where the confusion lies.

5394. Re: Circular polarization... does it have to be synchronous??

Newsgroup: rec.radio.amateur.antenna

From: Dave <noone@nowhere.com>
Message-ID: <blE%k.929$7I6.926@nwrddc01.gnilink.net>
Source record: 19118

I thought i had myself convinced that it would work, but then talked myself out of it... and went back to the books.

In my opinion, no, rotating a plane wave, even at the same frequency that it is oscillating would not create circular polarization. It would create a rotating plane wave, but it lacks half of the field components to be circular. The key is in this quote from ramo whinnery and van duzer's 'fields and waves in communications electronics': "if there is a combination of TWO uniform plane waves of the same frequency, but of different phases, magnitudes, and orientations of the field vectors, the resultant combination is said to be an elliptically polarized wave" (emphasis mine). This is of course the generalized case of the circular one that would require them to be of the same amplitude and 90 degrees out of phase as they note a few paragraphs later.

The key is the 'TWO' that I emphasized. If you trace the E field of a single rotating dipole that is rotating at the same frequency as the rf driving it you would still see the E field oscillate in amplitude at the original frequency. So as it propagated, even though the direction of the E field would follow a circular path the amplitude of it would change at the same rate, so there would be nulls in the E field every 1/2 cycle... in a true circular polarized wave the E field is a constant magnitude, it just rotates around the axis at the given frequency. you can't get that from a single dipole no matter how you rotate it since there will always be two zero crossings every cycle in the E and H fields.

i quickly scanned a bunch of the mail, i'm a bit behind in my reading so please forgive me if someone already came to this conclusion and i missed it.

Oh, and i briefly saw something about DC fields... actually i 'think' that if you put a 'dc' charge on a dipole, lets just separate two charges by some distance and start them rotating about a common center... that MAY actually create a circularly polarized wave. but i would consider this a degenerate case of the general problem. Even if you used an ELF rf signal to drive the dipole you would get zero fields every 1/2 wave which wouldn't work... with the pure dc charge you have a constant E field that is rotating, and 2 accelerated charges to make the corresponding H field. I think this works because there are 'TWO' rotating charges that each contribute to the resulting wave.

Hi Fred,
The first thing to understand is that for the most part the CB 5/8, 6/8, 7/8 antennas have nothing to do with the actual height. Manufacturers started claiming these lengths because the CBers believe(d) longer is better. At least for the mobile antennas the 5/8 etc referred more to the length of the wire used in the antenna- electrically, they were all 1/4 wavelength antennas.

You guys really get me. You claim everyone is a conspiracy nut ...
perhaps you are correct--but, it would seem everyone BUT you. And,
perhaps your definition of "conspiracy nut" is something I hold in esteem.

First and formost, conspiracy is involved in most of what I do. I
conspire to raise my salary to the highest possible, I conspire to get
the benefits possible. I conspire to beat the system, legally, at every
possible turn I can. I conspire to see my family and friends served
before all others. I conspire to have the best looking resume possible.
I conspire to save every dime I can. I conspire to leverage every
possible asset I have to the maximum.

I know "conspiracy" exists "on the job", I was a union steward in my
late 20's and early 30's. If you don't think I have seen REAL
"conspiracies" on BOTH sides of the fence--then conspiracies are only in
my imagination. Perhaps Hoffas' death is only that? Perhaps the
Kennedys were not in a "conspiracy" to get Hoffa?

Now, what do you idiots do? Tell the world everything? (i.e.,
broadcast your punches?) Have no secrets? I mean, certainly, a retard
has fewer than a scholar! Could just be, I guess. This is what your
implications bring to my mind ...

Now, you, indeed, may be just as stupid as you continually shout from
the mountaintop! But, you make a very grave mistake--I think those
"like me" out number you by a good 10,000:1.

P.S. Frequently, I fall asleep working on my next "conspiracy" to get
me and mine ahead ... if that is nuts, so be it. Competition is high,
this economic disaster will only increase it; You can either play or
pay. From the market, looks many choose to pay.

Regards,
JS

It's a cinch we can't trust the regular media to properly cover this
administration because they even overtly promoted it, while at the same time
slamming the current administration over the war. The inability of the
previous administration to deal with it and the terrorist acts that were a
product seem to have been lost in the shuffle. Here the guy who was in the
middle of it tries to come clean:
http://www.theatlantic.com/doc/200401/pollack

Then there's the Fannie Mae/Freddie Mac impending disaster that was covered
up over and over until it finally came home to roost and has goofed up the
world economy.
http://www.youtube.com/watch?v=hN31-nKndg8&feature=related

And now they are there to clean it all up? Give me a break. Be very afraid
when people are promoted for bad behavior and bad judgment.

I must differ. I think their reporting documented true failings of bush
and govt.

I also believe, their reporting depicted the true hope the "down
trodden" wish to place in Obama ... they are just sorely tired of being
sick and tired ...

Hi Fred,

6/8th and 7/8th wavelength at 10M would not have the best low angle
charateristic. At the longer wavelengths it should get progressively
better (as you may tell from EZNEC demo).

7/8th wavelength at 10M may also be hard to match with your ATU, but
worth a try.

Shorter antennas for longer wavelengths may find more loss in the ATU
than you would care to have, but a 5/8ths at 10M might be the best
work-around; and the shortest you should go.

> previously determined.

This seems a distortion of the facts. The addition was seen as the
forces between
current and the force between static particles which was in fact a
confirmation of the the speed of light.
My understanding of the term eddy current with respect to waves was
that it was ,made much later.
But the realization of the connection to light should have really
been recognised by Maxwell as a displacement of particles
and not waves since the presence of particles is predetermined. This
lack of understanding alsio helped the incorrect determination of
light
being a formation of waves instead of particles. This by the way also
cements the validity of changing Gauss's law of statics to a dynamic
field to equate with Maxwells laws which also confirms the presence of
particles. Another correlation to my theory is the interaction of
particles with the Earths magnetic field to produce Aurora or Northern
Lights i.e. particles bombardmentnot waves, Same goes for light
created at the center of a tornado which in itself
is the "eddy current" of a storm where againb light is seen as a
lightning strike where particles plus moisture is drawn into the
stratoshere an d then become separated. The evidence just piles up
that radio communication, radar and light itself is that which comes
from particles ala Neutrinos and NOT from the formation of magnetic or
electrical waves. And that Einstein was correct in his assertion that
radiation held the key for the Universal laws of all the sciences of
nature.Later when Foucalt discovered "Eddy current" which he
associated with water eddy currents it then came into use as a non
destructive material measurement system together with use in aluminum
sorting in scrap yards which in essence is a macro demonstration of
particle presence in radiation., again a vindication that the Maxwell
addition was wrongly assumed a wave structure.

I won't comment on your following statements as it is lost on me why
you have quoted them and the point of stating them

I tthink you have to go back to the beginning of this thread as again
you are talking out of context.
My statement referes to the current path on a fractional waqve antenna
when it reaches the top.
My point was that the current then procedes to the INSIDE of the
radiator where the AC current cannot produce
an eddy current and thus the opposition to current flow in the centre
is just a copper loss i.e.resistance.
This statement was made in requesting a possible different current
path from the top of the radiator
that provided a lower resistive path. I.E I pointed out that the
impedance dropped linearly with respect to radiator length
and thus I wanted a mathematically demonstrated different path that
would counter my initial assertion.

I think I have stated what skin depth is and what created it many
times so I won't respond
to the above paragraph

>
> Look for "skin effect" in any edition of Terman and you will find
> diagrams illustrating the various magnetic flux paths inside the
> conductor which cause skin effect.

I believe that the Wilkedia URL and Ian's supplied scanned page
is adequate descriptions where the initial supplied current is the sum
of the two currents in the circuit one of
which is Maxwells determination of displacement current i.e.a current
that displaces while providing an accelleration to PARTICLES (charges)
from the surface of a radiator.
If you can give an specific answer in mathematical form to the initial

question asked it would be apreciated
Other than that there is no need for continuation of this thread.

The physical length of those antennas available over here are 6.5m, 9.1m and
9.5m. So any height between 6.5m and 9.5m would be possible.
It is an alternative for going to a DIY store to get aluminum tubing.

> The other problem is if the reactive component gets too far for your

My remote ATU (Pi matching) has an inductance range from 0 to 63uH and the
capacitance ranges from 0 to 6300pF

Obtain a Solarcon A99. It will behave exactly as you have described, even with a built-in tuner. BTDT. Put it up about 20'. It will suck on 40 meters, but it will work. 20 meters isn't the best either, but it is usable. 17 meters on up it will work very well.

With 100 watts I could work 15 & 17 meters into Europe from NJ in the USA, with headroom to spare. Yes, the bands were open, but they were crowded at the time. I worked Austria as though they were next door.

>Do you have any comments on this?

Yes, the manufacturer has told you that the receiver sensitivity is -96dBm.
(no doubt for a particular BER, which aslo equates to a particular SNR).
Without knowing more about the internals of the receiver you cannot work
back to a NF unless you acuually know what SNR equates to the BER that the
manufacturer stated the -96dBm at. Using Shannon most likely give you an
unreliable optimistic answer.

>> If you know the rx sensitivity is -94dBm at the data rate you require,

No it dosen't unless you know more about the receivers and the actual SNR
that they require for a specific BER. Shannon will not tell you that, it
will just give you the 'best possible case' for a particular bandwidth,
which may well be a long way from the truth.

Yes and you proved just that!! Path loss 96dB, rx sensitivity -96dBm, 0dBm
tx power, equals receiver operating at its sensitivity limit. So what's the
problem??

> > Testing other distances, say 300m, we get a maximum transmit power Pt

>power allowed to reach the max data rate of 250 kbps (upper bound on
>power). Therefore, the transmission isn't possible. It wasn't for 0
>dBm.

I a sorry I don't understand what the hell you are on about. All you need to
know is the path loss at 300m, you aready have the rx sensitivity of -96dBm
so it is a simple subtraction to find the Tx power required (which will be
less than 0dBm).

>> Your maths is quite simple; you have the rx sensitivity, and can work out
>> the path loss, thats all you need to do, take one from the other and you
> >have the required tx power.
>
>That's exactly what I'm doing. The NF is included in the receiver
>sensitivity and the transmit power required to reach the receiver
>sensitivity is greater than the power I'm allowed to transmit at
>because of the 250 kbps maximum for the technology.
>

That is just not correct, you proved that the power required to reach
sensitivity limit at 500m was 0dBm, which is OK because that is you max tx
power.

At 300m you obviously require less tx power, so lets do the maths:

path loss at 300m, 2400MHz is 90dBm

so required tx power is 90 -96 = -6dBm which is less than your 0dBm max tx power - no problem.
-6dBm equates to 2.5e-4W or 0.25mW.

If you are trying to say that the -6dBm figure is greater than the number that you worked out using Shannon for a particular bandwidth and data rate once you take off the 90dB path loss then you have to look at the accuracy of your Shannon calculation.

You said that you Shannon Calculation produced a "reasonable transmit power of 1.6 uW", to achieve 250kB in a 5MHz BW. Now 1.6uW = 0.0016mW = -28dBm this does not seem reasonable when the manufacturers are quoting -96dBm!!! You must go back and re-consider your Shannon calculations, this time taking the actual receiver characteristics into account, such as rx NF, the real noise bandwidth, number of levels in the modulation scheme etc., etc..

Regards
Jeff

Yes, you don't want to get much longer than 5/8WL on
10m and you don't want to get much shorter than 3/16WL
on 40m. 22 feet is a good compromise length. At my
previous QTH I used a 22' monopole with the feedpoint
elevated at 22' with four 22' radials sloping down
at 45 degrees (also used as guy wires) and fed with
an SG-230. It worked like a charm for transmitting -
noisy on receive. Here's some information from
simulations:

22' Monopole with 22' elevated sloping radials:

Band: Gain: Take Off Angle: Feedpoint: ~Tuner Loss
40m: 0.53 dBi: 22 deg: 24-j229 ohms: 0.9 dB

Any time you nick a solid copper wire it will be severely weakened and
will likely break.

Dittos, can short internally too.

If it is anything important, the cable should be swept or at least checked for return loss at a higher frequency. Just in case the parts were mismatched out of the bag. Quality control can be a batch problem even in the high end stuff. Good help is hard to find.

I learned to make cables while assisting installation of a Doppler VOR facility . We were sweeping the pre-made cables that came with the system and finding a lot of them bad. We cut open a few of the bad cables and founnd the center conductor was not in the center of the cable. All of a couple of hundred cables had to be remade and cut for proper phase. The other grunt worker Dust Craig and I became very proficient at putting N connectors on RG-214 and using a vector voltmeter.

Ian
I never stated that you supported anything with respect to my ideas.
What you supplied with respect to skin effect was a coroberation of
the Wilkpedia definition which I stated WAS correct
also in the face of a statement that said otherwise. And I thanked you
for supplying it and no more. You may call me delusional as a sample
of free speech but you like the others have never
supplied an iota of evidence that shows that my ideas have zero merit
and thus are indulging in childish attacks.
I know that you posses the AO antenna computer program and feel very
comfortable with the fact that you are capable of putting in a one
liner that shows
that a radiator for maximum efficiency will be devoid of parallelism.
Unless you initially guide a antenna optimiser towards a planar design
the program will respond with a non planar design That is a fact and
is not delusional. Statements like that is no more than support for
the many talking heads.
This is a ideal place to point out once and for all a basic fact that
points to the feasability of my analysis.To deny or try to cover up
this computor fact with respect to the avoidance of a planar design
because of the addition to general laws by Maxwell is understandable
by those who do not have the means to challenge the books is
understandable but for you there is absolutely no excuse and shows a
dependence on emotion while at the same time pushing aside scientific
fact a fact that that is undeniable. A planar design is a
approximation with respect to Maxwells laws. A antenna omptimisation,
if allowed, will always respond with a NON planar design to conform
with all aspects provided by Maxwell's laws which I might add includes
the addition iof the "weak" force as suspected by Einstein.

>Can you say more about this? Or point to some web discussions / photos?
>Thanks.

There's not much to say or show. The usual example is the common
RG-6/u cable TV coax, that uses the solid center wire as the center
pin of the F connector. By necessity, the center wire is rather
stiff. There's also no way to immobilize the center wire as there
would be no room for the mating jack. If the rotary razor blade wire
stripper or half asleep tech with the wire cutters manages to nick the
center wire, chances are good that moving the cable around will
eventually break the center wire at the nick.

Crimp type BNC plugs are also susceptible in the same area. The
difference is that the center pin is either crimped or soldered. The
center pin is also supported by the Teflon insulator. However, if the
coax is moved constantly, as is common with test cables, any nicks in
the center wire will eventually turn into a break. This one is
particularly insidious because it occurs inside the connector, where
both ends of the break are supported in place, resulting in an
intermittent, rather than a clean break.

Big fat center wires are not immune. They just have a different
problem. When one of the heavy stranded center wires from RG-8/u
style coax breaks at a nick, it's usually perfectly positioned to
short to ground. In the common PL-259 UHF connector, the coax end of
the break is not supported, resulting in a difficult to find, and
impossible to see, intermittent.

In my limited experience, the tools that cause the most problems are
the ones with the built in razor blades:
<http://www.mytoolstore.com/ideal/ide08-07.html>
<http://www.mytoolstore.com/ideal/ide08-06.html#coax>
<http://www.mytoolstore.com/ideal/ide08-08.html>
<http://www.fab-corp.com/product.php?productid=1665&cat=281&page=1>
<http://www.hyperlinktech.com/item.aspx?id=879>
(Note the huge variation in pricing)

As long as the blades are sharp they work just fine. However, when
the blades get dull, the user tends to bend the cable to assist in the
cutting, which sometimes results in a nicked center wire. Cleaning up
the stripping job with a pair of diagonal cutters also causes
problems. Stripping is also difficult with Teflon insulated wire and
non-wicking insulation (marine coax), where the dielectric materials
are bonded to the conductors. The best way to strip these materials
and to be sure not to nick the wires is with a thermal wire stripper.
<http://www.teledyneinterconnect.com/products/wire_strippers/wirestrip.asp>
I got lucky and ended up with pile of these from some aerospace
surplus outlet. Very handy. Just take care not to breath the fumes.

However, if you're working with LMR-400, LMR-600, or larger, the
blades of the thermal stripper cannot expand wide enough to fit the
coax cable. Therefore, I suggest getting the correct Times Microwave
EZ-Strip coax stripper for these cables:

BTW censors who have a problem with this discussion can find a different tree. It is well established that these topics are routinely hijacked immediately. But in reality the Subject line of this thread must be a troll for political discussion since universities, the media, business, government are such targets for subversion.

Bush's failings, indeed the failings of the Republicans in general have been their dumbfounded reaction to these criminal (or ignorant) acts of democrats. The brazen point was made to regulators in the video above. He was actually complaining that democrats needed more oversight to check their own bad behavior. In reality it is hard to promote freedom and then have to take a firm hand against those who exploit it. It is a big quandary. Big government leads to corruption and domination, not big enough and it gets overrun. Without widespread moral patriotism, freedom is lost. We have

lost this to demoralization.

Case in point, Nancy Pelosi seem to have in mind that the big three should do what they are told by a dominant government overseer and be immediately profitable to her tastes while they are dis-advantaged in the marketplace by the active redistribution of wealth of the unions. Granted, management shouldn't expect golden parachutes, but the lavish retirements of union employees and high wages are a major drain on a crippled enterprise. It really sounds like a plan to pay off the employees, cover up the problem and throw jobs under the bus. Management will take the blame for the failure and all the employees who are suddenly out of work with big mortgages will hate them as they lose their mansions. I know a few right now. The real answer for all this is immediate and localized accountability at all levels. Bring back bonuses and commissions for productivity and loss for loss. Not the unmanaged situation that exists now where exploitation and failure goes unchecked at all levels, and go crying to someone for money to clean up the wreckage. People need to have expectations of them or they won't succeed. Unrealistic expectations just lead to demoralization and failure.

> I also believe, their reporting depicted the true hope the "down
> trodden" wish to place in Obama ... they are just sorely tired of being
> sick and tired

This is like the people out here who get fired by their leftist bosses and are told it's Bush's fault. Maybe if he shouts his indignation at Bush loud and hard enough, the people who smacked him down will take pity and give him his job back. This is like the battered wife hoping she can do better next time, because her husband says he loves her and he will change, although the beatings are worse every time. This is called demoralization. It is a psychological process that conditions peoples reactions so that they are unable to process fact, only react to stimuli. The next step is destabilization. How is it in our best interest to destroy the economy and throw record numbers of people out on the street? If people don't wake pretty quick, you and I both will be taking a bullet in the head, because I am a dissident and you because they won't have a need for you when you finally realize were we are going. This realization must come from Republicans and Democrats because we have been conditioned to extremes. Socialists think we need more intervention, smothering, nationalist health care and free drugs, free housing, loss of freedom and choice so we don't endanger ourselves and our children. Where does teaching them homosexuality and abortion fit in? It certainly facilitates conquest. Capitalists are taught that Greed is good and that it is OK to prey on those around us. This is where Rush Limbaugh does harm. It fans the flames of class envy. The real answer to all this would be a shift in our thinking as voters, legislators, and people at all levels in our government. In the true spirit of patriotism and moderation, a conservatism could emerge that has a healthy skepticism, a realization that no one should be trusted too much with our welfare, and that we should first count all our fingers before shaking hands in business. It is my hope that somehow enough people who are resistant to the current conditioning can transcend the bi-polar thinking of this nation before civil war breaks out.

The only fault with that conspiracy is that without moral restraint, the
10,000 kill the 1 who is supporting them. Otherwise the best you can hope
for is a balance of terror.

FWIW, http://dixienc.us/28FtVert/28FtVertical.htm
might help you make some decisions.

Unless you already have the materials I suggest you build with ten
foot lengths of chain link top rail. The last time I priced it at the
home improvement store it was $11 per section.

If it were not for the price of the tuner it would be a cheap antenna.

Every time I tinker with it I learn a little more.

If DX is your thing, go for the low angle radiation for your favored
band. DX is of little interest to me so the high angle radiation on
some bands just gives me a different set of Hams to work.

It is beginning to look like the need a "Superior Grand Jury." Perhaps
a couple of reps from each state which over see the president on
down--no matter if the republicrats or the democans are in charge ...

But then, in my county, even the sheriff and city police are corrupt!
How about "drafting" them too. Each citizen does a tour in the
police/sheriff ... Or, in other words, if we can't even keep our own
house clean, how are we going to keep the countries?

Sometimes, I am a bit slow on the uptake--I just don't get that thinking.

Since when is responsibility and competition a bad thing? Isn't it what drives small business AND corporations--even the largest. I mean, when I had to work for corps and pick-the-bones to survive, everyone was attempting to get someone fired--to give family, relatives or friends a shot at the job! ROFLOL Control freaks were the norm, NOT the exception!

I only thank gawd I found a path out ...

Experimenting with a too long antenna on 10M can be fun. I did a 1.25
wl antenna and got some interesting results during band openings. You
get to talk to where everyone else isnt. I felt like the band had
opened just for me. Of course this isnt the norm.

> product.
[snip]

I agree, there are certainly several "commercial" high priced muliti-physics
software packages
available on the market that cost 10's of thousands of dollars per 'seat',
and... I'll bet that there
are a few more "in-house" packages developed within the defense industrial
community.

[snip]
> Certainly, there IS a lot of modeling of EM waves from moving objects

> (emphasis mine). This is of course the generalized case of the circular
> one that would require them to be of the same amplitude and 90 degrees out
> of phase as they note a few paragraphs later.
[snip]

Yes! We all know that nothing is really "rotating" in circular
polarization,
rather circular polarization is merely the presence of two separate linearly
polarized waves that are differ in time phase by 90 degrees and mutually
oriented at 90 degrees (space angle) to each other.

A circularly polarized wave excites a linearly polarized antenna equally
well when oriented at any arbitrary angle. In fact a fundamental
"experimental" test to determine if a wave is circularly polarized is to
receive it (measure it) with a linearly polarized 'test' antenna while
the test antenna is rotated. If the signal strength received on the linear
test antenna is the same at all angles of orientation then the received
wave is circular.

Of course, the useful 'discrimination' property of circularly polarized
waves is most evident when they are used with circularly polarized
antennas not linearly polarized antennas. A circularly polarized
wave of a given chirality, will be received at full strength on a
circularly polarized antenna with the same chirality and will be
rejected (null signal) on a circularly polarized antenna of the
opposite chirality. This property provides the most useful
applictions of circular polarization.

[snip]
> The key is the 'TWO' that I emphasized.

[snip]

Yes!

> If you trace the E field of a single rotating dipole that is rotating at
> the same frequency as the rf driving it you would still see the E field
> oscillate in amplitude at the original frequency.
[snip]

Yes, if by 'trace' you mean measure with a linearly polarized antenna.

And you would see exactly the same with "trace' with a circularly
polarized signal.

In other words, there is no difference between the wave generated
by a circularly polarized antenna and a wave generated by a linear
antenna mechanically rotated at the signal frequency.

In each case if you placed a linear receiving antenna in the passing
wave front, and hooked and oscilloscope up to the linear receiving
antenna terminals you would observe exactly the same received signals.

[snip]
> and you would observe the same w So as it propagated, even though the
> direction of the E field would follow a circular path the amplitude of it
> would change at the same rate, so there would be nulls in the E field
> every 1/2 cycle...
[snip]

Yes!

[snip]
>in a true circular polarized wave the E field is a constant magnitude,
[snip]

NO! Unless you are referring to say the root mean square magnitude of
the E field, the actual instantaneous magnitude of the E vector oscillates.
The E field of any electromagnetic wave is never constant
it is constantly oscillating in a plane transverse to the wave direction
at the RF 'carrier' frequency.

[snip]> it just
> rotates around the axis at the given frequency.
[snip]

Yes indeed! In the case of circular polarization, there are actually two
separate phase locked linearly polarized (vector) E fields oscillating at
the same frequency but in simultaneous time phase quadrature and space
phase quadrature.

And, here is the important point...

The 'vector sum' of these two orthogonal waves adds up to give an E
vector that appears to be rotating.

Remember that any vector can be resolved into or synthesized from
the sum of other vectors. For example in two-space any vector
can be resolved into two other perpencicular vectors.

(x, y) = (a, b) + (c, d)

Now (a, b) and (c, d) may be linear, but if they are of the form
a = A cos(wt), b = B sin(wt), c = C cos(wt), d = D sin(wt) their
sum (x, y) will appear to be rotating.

Think of the 'projections' of the spoke of a rotating bicycle wheel!

[snip]
> you can't get that from a single dipole no matter how you rotate it
[snip]

Yes you can, see above.

[snip]
> Oh, and i briefly saw something about DC fields... actually i 'think' that
> if you put a 'dc' charge on a dipole, lets just separate two charges by
> some distance and start them rotating about a common center... that MAY
> actually create a circularly polarized wave.
[snip]

Yes it should, but that's not the particular/specific application or
scenario
that I was originally proposing.

[snip]
> but i would consider this a degenerate case of the general problem.
[snip]

Agreed!

My original point was that there is essentially no difference between the
wave
emitted by a conventional circularly polarized antenna (say axial mode
helix [W8JK], or a turnstyle) and a linear antenna spinning mechanically or
spinning
by electronic scanning means, with angular velocity equal to the carrier
frequency.

My claim is that here simply is no way to determine
the difference by any physical measurement. The emitted fields are exactly
the same.

We know that there are good applications for 'conventional' circular
polarization where the rate of field 'rotation' is synchronous with the
carrier frequency.

I was just wondering if there are any good applications for circular
polarization when the rate of field rotation is not synchronous
with the carrier frequency, and if so, how well one could
discriminate between such waves rotating at different angular

velocities.

Harold,
Yes I do need an audience of radio hams of which a very small minority
is able
to operate a computer program for antennas with a optimizer. I may
well be a nut case as you say and delusional
as others would say but for many years I have presented the same
problem
to this group which in itself provides vindication to my thinking.
Over the years I have pointed out to this group that an optimizer
program (one of which is free on the web)
will always discard the planar design in favor of a design that is in
equilibrium. Now I am not a computer programer
sio I am not resposible for the programs that push aside planar
designs such as the Yagi, I am just pointing out a fact.
Now I am not willing to take the aproach of garbage in garbage out but
I am willing to investigate why and present my findings.
I have done that and regardles what you think of me as a person as
radio hams you should be concerned about accepted programs
on antennas putting out what you consider as garbage. Now I understand
that many are not able to tackle such a problem and in fact many
cannot even operate a computer. But this is a newsgroup for the
discussion of antennas and many feel they are competant to determine
what is garbage or not without the use of a computer. But surely some

must realize that those who one suspects is really an expert in antennas and computer programs
not one has inserted a one liner in a program to check out the info that I placed before them.It has been several years of name calling by those who are not skilled in the art but total silence from those that are skilled because they cannot provide a reason for such results and at the same time cannot aliign themselves with the naysayers. Think about it guys, you want to shut me up then why not explain the anomoly? Years ago hams were happy to accept outrageous gain figures advertized in QST and advertizers knew that hams would not question it and they were correct as the present situation shows.
You state I have been a problem for years with respect to this yet nobody as yet has stated that the programs do not take this path or tried to explain why.
It takes 5 minuits to check with a one liner and for a hero to emerge to chop me off at the knees, but not one is willing to come forward and thus lose his place in the pecking line of pseudo experts....not one. Thus those on the group of lesser abilities gain confidence in calling evrything trash while those that can do remain silent. They know the computer programs are acting this way. Their silence infers that the programs are doing something "wrong"
Harold, turning a blind eye to what i have informed others will not force me to collect coals from Newcastle as I am not going away so a few may maintain an un truth. If you are not just a talking head use the free program available on the net and find out the truth for yourself instead of being a lemming.
Art

5442. RE:"Round" quad

From: Harry H <harryharms@hotmail.com>
Message-ID: <jA00l.1153$cu.366@news-server.bigpond.net.au>
Source record: 19166

I am wondering if its possible to build a 6 element "round" quad antenna,
that is the elements are circular instead of square.
I want to use it for DFing and have the centre frequency of 438 mhz.
I will be mounting the elements on an insulator above the boom, will the
boom have to be non conductive?
I intend to use 1/8" alloy wire for rigidity, and make the element mounts
out of insulating material so they can be slid along the boom, will the
frequency to wire diameter ratio have any effect on the length of each
element?

Before retirement, many of my instrument designs had to work in
high-temperature, corrosive environments, so I frequently used PTFE*
insulated wires. I purchased one of the Teledyne thermal strippers and was
VERY pleased with its operation. The next year I found one for sale at a
hamfest for $5. I snapped it up immediately for home use. If you work
with small gauge wires, and especially with PTFE insulated wires, I
strongly recommend these units.

Well, if this is a defense, at least it is rational (doesn't mean it
is logical, however).

>Over the years I have pointed out to this group that an optimizer
>program (one of which is free on the web)

And one that Art will never divulge the name of - with his natural
inclination to suppress information. I could be wrong in that he
might be actually suborning the circulation of software pirated from
vendors. As his experience is limited to one package from the 1980s,
and that author has refused to market it anymore because of piracy, it
is rather hypocritical that Art suggest it can be freely obtained.

Art can immediately nullify this tarnished image of supporting
computer piracy by naming this so-called "free optimizer" - but I will
bet dollars to donuts that he would rather embrace this form of
illegality than utter that "free optimizer's" name.

>will always discard the planar design in favor of a design that is in
>equilibrium.

In fact it will NEVER discard any design for one that is inferior!

>Now I am not a computer programer
>sio I am not resposible for the programs that push aside planar
>designs such as the Yagi,

A computer user is probably more dangerous than a computer programmer
when it comes to this erroneous usage.

>I am just pointing out a fact.

Making a mistake is a fact. Publishing it as the tool's fault is
called coppin' a plea.

>Now I am not willing to take the aproach of garbage in garbage out but
>I am willing to investigate why and present my findings.

Another strange defense garroted by the fantasy of "findings."

> And you would see exactly the same with "trace' with a circularly
> polarized signal.

no you wouldn't. with the rotating dipole the E field would have zero crossings every 1/2 wave even as the direction rotates. with a real circularly polarized wave the E field is a constant magnitude and just changes direction. if you break down the wave into 2 orthogonal linearly polarized waves the zero crossings in one line up with the peaks in the other so the resultant vector magnitude of the E field is a constant... only the direction changes.

>
> In other words, there is no difference between the wave generated
> by a circularly polarized antenna and a wave generated by a linear
> antenna mechanically rotated at the signal frequency.

yes there is, you are missing 1/2 the wave components.

>
> In each case if you placed a linear receiving antenna in the passing
> wave front, and hooked and oscilloscope up to the linear receiving
> antenna terminals you would observe exactly the same received signals.

Only at multiples of 1/2 wave distances from the transmitting antenna. When the transmitted peak E field is oriented properly for the receive antenna you would get a max receive signal. But when you orient the tx antenna so the max in the tx E field is perpendicular to the rx antenna you get a null. This pattern repeats every 1/2 wave... again, a real circular signal would have the 2nd wave component at right angles to fill in those nulls.

>
> [snip]
>> and you would observe the same w So as it propagated, even though the
>> direction of the E field would follow a circular path the amplitude of it
>> would change at the same rate, so there would be nulls in the E field

>> every 1/2 cycle...
> [snip]
>
> Yes!

Ah, so you agree here, but not above... this is the key to the difference. there are zero crossings of the E field in the rotating plane wave, but NOT in the circular wave... hence rotating plane waves have nulls every 1/2 wave.

>
> [snip]
>>in a true circular polarized wave the E field is a constant magnitude,
> [snip]

> it is constantly oscillating in a plane transverse to the wave direction
> at the RF 'carrier' frequency.

no, the E field is a constant magnitude in a true circularly polarized wave, only the direction changes.

>
> [snip]> it just
>> rotates around the axis at the given frequency.
> [snip]
>
> Yes indeed! In the case of circular polarization, there are actually two
> separate phase locked linearly polarized (vector) E fields oscillating at
> the same frequency but in simultaneous time phase quadrature and space
> phase quadrature.

right, there are TWO orthogonal waves... with a rotating dipole you only have ONE wave whose polarization changes over time. put a circularly polarized wave through a polarizing filter and you still get a signal no matter what the orientation. put a polarizing filter in front of your rotating plane wave and you get a signal that depends on your distance from the antenna.

>
> And, here is the important point...
>
> The 'vector sum' of these two orthogonal waves adds up to give an E
> vector that appears to be rotating.

Right! But go back to the books and look at that vector sum in detail. the magnitude of it is a constant, only the direction changes. in a rotating plane wave both the direction and magnitude change because there is no 2nd field component to fill in the zero crossings.

>
> Remember that any vector can be resolved into or synthesized from

> sum (x, y) will appear to be rotating.
>
> Think of the 'projections' of the spoke of a rotating bicycle wheel!

RIGHT! so take your rotating dipole and look at it from even multiples of 1/4 wave away... lets assume that the max E field from the tx antenna is when it is horizontal, and min when it is vertical.... remember, the antenna rotates 90 degrees as the tx rf also goes from peak to zero crossing... so the zero crossing will always be when the antenna is vertical and the max will always be when the antenna is horizontal. So, at even multiples of 1/4 wave you see the max E field in the same orientation as when it was transmitted, horizontal. Move another 1/4 wave away, so now you are at an odd multiple of 1/4 wave. now that max E field is vertical and the minimum is horizontal so your horizontal rx antenna sees the minimum field. Without that 2nd wave at right angles you have a null in the pattern, the 2nd wave from a real circular wave would fill in that null and you would have a constant signal amplitude.

>
> [snip]
>> you can't get that from a single dipole no matter how you rotate it
> [snip]

yes there is. a polarizing filter or just by moving a linear rx antenna
will tell you which is which.

>

maybe it could be used for some kind of distance determination by rotating
at a slightly different frequency than the carrier frequency. that would
create a null when measured from a linear rx antenna that moved along the
line of sight at the difference in frequencies. it may be hard to calibrate
and measure since the tx polarization vs time would have to be known so you
could calculate how much rotation there has been at your location... and it
would of course fall apart if it wasn't line of sight and there were any
reflections.

yeah, and art thinks he is the only one who ever let an optimizer run until it went into an unrealizable super gain state. most of us have learned to constrain them properly so they give buildable results, but not art, he keeps trying to explain how they use the same well known maxwell equations, but in secret have this hidden weak force that makes them give results that only he can understand.

We have a couple at work and I think they are the greatest thing since
sliced bread and I wanted one for home use but didnt have quite the
need to match the cost.

Not being lucky enough to find one for $5 I ground a notch in a hose
clamp and fastened it to my soldering iron. It works well on just
about anything except PTFE.

From: Bob Bob <bob3bob3@suddenlink.net>
Message-ID: <5gf716-51c.ln1@p400bob.personal.cox.net>
Source record: 19172

Hi Harry

Many years ago scaled a quad from the RSGB handbook from 1296 to 432MHz. It used "round" elements of flat aluminium about 15mm wide for parasitic elements and a copper piece for the DE. All were directly bolted to the boom (30mm dia Aluminium pipe) with no insulator.

The DE was fed direct connect balun style with the coax shield soldered at the element/boom point, then crossing to the other side of the circle and splitting inner/shield to each side of the element.

Worked well! (Was 23 elements I think)

I would say yes to the length question, but I dont have a handle on how critical..

I also made a few circular/helix antennas which are for less critical dimension wise. That might be another option for DF mode...

Cheers Bob VK2YQA

Hi Pete

I dont think a rotating dipole with DC on it will generats a field that propogates. Your post reads as though you dont think the rotating DC dipole will producing a propogating Far Field. I read other posts that seem to indicate that others assume the DC spinning dipole will generate a propogating "far field". It is sad that I am so lazy that I cannot express myself using Cross Products. But, I submit that it takes more than rotating a dipole to produce a propogating far field.

I dont understand where the "Cross H" is generated by a rotating DC dipole, as required for propogation.

I dont understand why it requires more power to rotate a DC dipole with increased voltage on it, as required to account for the increased power.

>element?

Here's a pair of 27 Quad -loops I built for contesting. They were scaled
from the G3JVL 23cm design. They worked really well. Gain of each is
19dBi measured on sun-noise.

Http://www.b-howie.demon.co.uk/70cm%20ant.jpg.

An antenna programme like MMANA will handle Octagonal loops (which is
close enough) if you want to optimise before building. I've got an MMANA
model for the 27ele , however the antennas are constructed out of strip
elements, so I had to guess it a bit.

The boom can be conductive as long as the insulation is at least half
the boom diameter. Mine are bolted to the boom ; it's a low voltage
point. Driven element is copper strip fed by flexi-rigid cable at the
top and fed through the bottom on a bush. Matching is done by making
the DE slightly oval by squashing it then soldering the flexi-rigid at
the boom

A question you need to ask is what's the receiver bandwidth. The
information might only be 250 kHz wide, but if the receiver is 5MHz
wide, it's seeing 13dB more noise, and it might not be able to "acquire"
the narrow band signal.

60dB path loss, 250kHz BW is 54dBHz, so kTB noise floor is -120dBm, for
a "real" receiver and cabling, probably 5dB worse, call it -115dBm. Add
the 60dB, and you need an EIRP of -55dBm.. (You calculated 6E-10W,
-62dBm.. that's reasonably close)

But, if the receiver is seeing the full 5MHz (or more) BW, then you'll
need more.. 13dB at least (-100dBm at the receiver.. Obviously, most
receivers don't do this well, or they're counting some S/N margin, to
get a spec of -94dBm)

Then, you'd need -34dBm (with the same 60dB path loss)

But I'll bet you actually need more...

Non-ideal antennas
Losses in cabling

Mismatch (the Tx may put out 0dBm, but if the antenna presents a 2:1 mismatch, it's not radiating 0dBm, etc.

And, the "acquisition" threshold might be different than the "communicate" threshold.

Thanks much. I checked my email this morning and found one person
asking me to sell them one of these strippers, and two more asking
questions about their operation. Apparently, there's some interest so
I'll post my answers.

1. You can find various thermal wire strippers on eBay, usually for
peanuts. For example:
<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=320323912948>
The problem is this style of stripper is only suitable for small
diameter wires and small diameter coax cables. RG-6/u can be done,
but it's tricky. Make sure you get the long jaws if you want
something fairly universal. The problem is not getting the jaws wide
enough. It's preventing the end of the coax cable from getting jammed

into the narrow part of the jaws.

2. Teledyne does make the TW-6 model, that's made specifically for coax cable.
<http://www.teledyneinterconnect.com/products/stripall/models.asp>
I have several of these. We used these in a production environment to strip RG-188/u with PTFE wrap insulation and dielectric. We tried using blades, but thermal stripping was far superior.

3. Note that most models come with various forms of power control. This is not mandatory, as I have become quite proficient at timing the push button for temperature control. However, if you want to avoid overheating, burned out tips, and meltdowns, make sure you get the temperature control. If the tips glow red, it's far too hot. Adjust the operating point with an infra-red optical thermometer,

4. You can make your own thermal strippers from a length of nichrome resistance heater wire and a small soldering iron. Remove the copper tip and replace with a piece of nichrome. I've also seen a production machine made from a plastic bag cutter/sealer and another from a foam cutter. A low voltage filament transformer and a variac can also be made to work. Obviously, some experimentation will be required, but it will get warm and eventually work. Nichrome wire is available at most hardware stores for repairing heaters, toasters, and telescope condensation prevention heaters. You will need to supply some spring tension as the wire stretches when it gets warm.

The problem with using wire is that it doesn't last very long. The large heating tips of the Teledyne strippers are sufficiently massive to survive for years of constant production line operation. I can't say the same for using wire.

I suspect that one of the handheld battery operated soldering irons, could be morphed into a thermal wire stripper by replacing the heating tip with a nichrome wire.

Yes. It's called a "disc yagi". It was commonly used for various
wireless TV schemes in the 1970's.
<http://www.supernec.com/diskyagi.htm>
<http://www.idealantenas.com.br/produto/yagi%20disc19/yagidisc19_ing.htm>

>I want to use it for DFing and have the centre frequency of 438 mhz.
>I will be mounting the elements on an insulator above the boom, will the
>boom have to be non conductive?

It should be non-conductive. You'll have plenty of entertainment
value figuring out how to run the feed line. I suggest a triangular
mounting contrivance rather than a stright pole. It keeps the coax
mostly out of the way, but also is more rigid than a stright pole. If
you're only going to have 6 elements, you can mount it by the
reflector end. However, methinks you'll want or need more than 6
elements in order to do direction finding. The big problem is
reflections off buildings and hills, You need good resolution to
identify and seperate these with a rotating antenna direction finder.
That means a narrow 3dB antenna beamwidth.

>I intend to use 1/8" alloy wire for rigidity, and make the element mounts
>out of insulating material so they can be slid along the boom, will the
>frequency to wire diameter ratio have any effect on the length of each
>element?

Ideally, the center boom should be an insulator but could also be
metal if sufficiently small diameter. A disk yagi doesn't use any
wire (except for the driven element).

Hi Harry

Your post seems to refer to making an antenna from wire or tube. Would you consider using an antenna modeling program, like EZNEC? Roy has a program that allows you to make loops of any size and shape with any spacing. It would be very easy to model any configuration you desire.

Really Jim,

Do you think the vendor would specify a bit rate capacity and then
fail to supply the needed bandwith?

Omar has a peculiar habit (much like our own home-grown trolls) of
focusing on issues that have been solved, and complaining (through the
veil of supposing "what-if") about the math behind them creating
confusion.

Part of this veil is Omar holds all the cards while revealing nothing
(another trolling technique). Simply consult:
http://focus.ti.com/docs/prod/folders/print/cc2431.html
and take any of the several links to specifications, applications,
block diagrams, schematics; and it becomes painfully obvious that any
confusion that Omar suffers, is that advice already posted in
abundance devolves to rather simpler issues than Nyquist, Shannon,
Hartley, or more exotic sources.

That's because everyone in the industry steals them, takes them home,
and uses them for the rest of their life. They're hard to find.

>However, I am having visions (sometimes I do that, yanno', must be the
>60's or sumthin'? <grin>) I see myself grabbing a small brad in a pair
>of needle nose, heating it red hot and running it about the diameter of
>a wire--in a pinch.

Won't work. There's not enough thermal mass in your hot brad to do
the job. The hot brad will need to hit the coax braid, or wire center
conductor, in order to thermally cut through the insulation. Copper
is a very good thermal conductor. As soon as the hot brad touches the
copper, the heat gets sucked out of the brad rather rapidly. It might
work if you're careful or very fast, but methinks it's not very
practical.

Of course, you can use a large block of hot aluminum or copper with a
cutting edge, but that would be potentially dangerous and certainly
rather messy if you mishandled it. Of course, you're welcome to try
it. Have burn grease, Band-Aids, and a fire extinguisher ready.

>Replacing the high tech brad as necessary ... <straight face>

Incidentally, I got my experience with hot wire cutters (and burned
fingers) at my father's lingerie factory in Smog Angeles. We made our
own as the commercial versions were seriously overpriced. My
childhood wasn't totally wasted.

Yep, it's all about the antenna. Hell, even a dipole tuned to the
midpopint of the band used for HD would get better performance.

Actually nothing works unless most people's attitudes are more level headed. Any overseers are subject to the same pressures the causes the ones in place to fail. I've known people that did ride-along only to wind up in prison or loony bins because they were nothing but bullet stoppers/sitting ducks and all the dope people knew about it. Somebody got to 'em. And too often the cops and court system are completely ignorant about WHY a crime scene, and just edit the how and who to what brings them a perceived victory. Even the cops you know have an abbreviated philosophy geared to survival. Although they are OK with you, the ones you don't know, automatically place you in the "subject" class of probable criminals. They are no longer required to support and defend the Constitution or the keep the peace, but to give everybody a bad day at their own discretion.

It's just like the Dope War. There is big money in it. Do you think people will let it go so easily? As long as people are stoned and dependent, they will tend to seek that even if is self-destructive. If you want to see what peer pressure can accomplish, google Jim Jones.

I still find this 1985 interview to be profound. The Psychology of it is most profound. It shows how gullible we are to suggestion and how easily and cheaply that can be exploited.
http://www.dailymotion.com/video/x32cxf_yuri-bezmenov
I couldn't tell you if they still seek our destruction, but after at least 2

generations of programming it has certainly gone on automatic.

This is the problem with utilizing a scorched earth plan. It's like a wildfire. Once you light it, you lose control of it until it burns out. It only cost $2 for a box of matches and $100 million in fire fighting cost and 500 homes destroyed and 20 deaths before it is at least contained. Then 20 more deaths and 50 homes lost to flash floods and mud slides.

Indeed if you study Russia's own propaganda, they paint a picture of the US as a crazy first strike threat, in order to feed the military/political priority in their lives as a matter of survival.

My only answer to all this is for conservative people (not reactionary) to establish their own media. All that is required is a challenge to unthinking mantras to wake people's thought processes. Just as the doper needs at least 6 months of rehab before the can even have a clear mind, and at least another 6 months of rehab to learn the basic mechanics of using it (or what's left of it). I would hope they lose their driving privilege and voting right for that much time too. It is my thought that the drug problem wasn't conceived by the Russians, but that they easily exploited our own compromise (decadence) and loss of common sense.

Sure.. it's the other way around though.. they might have a wideopen front end or IF (e.g. 5 MHz wide) and be looking for a narrow band signal in that big band.

Particularly if you have a system that supports multiple rates, and you want a single hardware design without adjustable bandwidth, your hardware has to support the widest band.

You're left with two design choices:
1) have a "minimum detectable signal" threshold that corresponds to the higher noise floor
or
2) Have a narrow(er) band detector (implemented in software or hardware).

the first is cheaper, and can be overcome by marketing

Well, this IS true.

The whole thing is quite well documented, although if one just reads the ad copy, it is confusing. Worse, if your manager asks why you can't do the high rate and max distance at the same time, and you have to resort to "laws of physics" arguments.

[snip]

What is required to generate electromagnetic radiation is any movement of electric charge such that there exists a rate of change of the positional acceleration
of electric charge. This can be derived from first principles from the Maxwell/Heaviside
equations. There is a section in the volume of Feynman's Lectures on Physics that
discusses this, and I believe that the previous editor of QEX magazine wrote an
article outlining a derivation of this a year or so ago.

In physics and dynamics the rate of change of acceleration is termed "jerk".

In terms of simple differential calculus, there is position ("x"), there is velocity
("v = dx/dt") the rate of change of position, there is acceleration ("a = dv/dt")
the rate of change of velocity, and there is jerk ("j = da/dt") the rate of change of acceleration. Expressing it in these terms, it can be said that it
it can be shown from the Maxwell/Heaviside partial differential equations that govern all of electromagnetics, that radiation occurs when ever electric
charge is "jerked". i.e. whenever the rate of acceleration of charges changes

either up or down.

Now in sinusoidal realms, where all the signals are assumed to be of sine wave shapes, we know from simple differential calculus that differentiating sine waves results in more sine waves. In other words a sine wave current comprises electric charges changing position according to a sine waveform, and so perforce is the velocity, acceleration and jerk of those charges. Hence
whenever electric current motion follows a sine-like wave there will be radiation caused by the sinusoidal 'jerk'.

Now there are more forms of acceleration than just sine wave motion.

For example when things have angular motion, there is centrifugal acceleration, and when things move on a rotating frame there is coriolis acceleration, etc... and so in general whenever electric charges are put in motion, the exception being simple motions where the third derivative of motion is zero, there will be radiation caused by that motion.

All of the above details are well known to most physicists who study electromagnetics, from first principles (Maxwell/Heaviside), these 'facts' are less well known to most (modern) electrical Engineers.

Consequently I find it easy to believe that the mechanical motion of any body with electric charge on it, be that charge DC or AC is highly likely to radiate electromagnetic waves.

All of this is difficult, actually impossible, to simulate with NEC codes like Roy's EZNEC since those analysis codes all assume a simple steady state fixed sinusoidal regime for the framework in which the Maxwell/Heaviside equations are solved. NEC does not provide for the simulation of antennas in motion! And so...

It is beyond the capability of NEC in general or EZNEC in particular to generate field patterns for rotating dipoles!

Othewise someone (Cecil maybe?) would already have run a simultation on EZNEC to refute my claims to being able to generate circular polarization by mechanical rotation.

In other posts in these threads on CP I have asked if anyone knows of any simulation software (generally would be in the category called "multi-physics packages" that can adequately simulate/calculate the fields for rapidly rotating dipoles driven by sinewaves at arbitrary frequencies. If so I'd like to know. And I'd like to simulate some of my "theories" just to prove my assertions.

Actually it may be easier to emulate (i.e. prototype) such a spinning dipole. In fact one does not have to mechanically spin a dipole to do this. One can generate the same fields as a spinning dipole by applying the "right" signals to two

orthogonal linear dipoles. i.e. a synthetic or phased array
beam former, that emits circularly polarized beams of
arbitrary rotation velocity.

Phased arrays can be elctronically scanned or rotated,
this is in fact how most modern STAP radars work, e.g.
Aegis, etc... and so one can electronically rotate emitted
waves in the same way. It's not cheap, but it can be done.

My curiosity is along the lines of if you could find a cheap
way of rapidly spinning an emitting dipole, what new
applications might arise from that.

As far as I can determine, no one has yet done the experiments
that I have been discussing here in these threads.

And so my suggestions/theories are met with comments
like, "It's never been done before, why would you want to do it,
etc, etc... ?

Why do I ask such questions?

Just curious or perhaps I'm just plain stupid!

But no one has yet been able to categorically refute my assertion.

Whenever charge is jerked there is radiation!

Food for thought.

What a lot of bafflegab. For one sentence movement is named,
described, AND inferred three times; and charge tied to two of them.

Peter, when the ladies say NO to you, they probably have to have it
annotated, indexed, and footnoted before you get it.

Message-ID: <Xns9B7383A459525nonenowhere@61.9.191.5>
Source record: 19195

All,

I refer to the diagram at http://www.vk1od.net/lost/Fig6.png which is from an article by the then VK2ZAB (now VK3EJ) on stacking Yagis.

I have highlighted two of the diagrams with a yellow background, and seek opinions on them.

Referring firstly to the left hand one:

I suggest that the figure is in error because the scenario is not ALWAYS wrong.

My contention is that at a single frequency, the phase inversion as a result of the left to right swap of one driven element (DE) wrt the other can be fully compensated for by ensuring that low loss feedline to one DE is an odd number of electrical half waves longer than to the other.

Where the low loss feedline to one DE is an odd number of electrical half waves longer than to the other, the Yagis are driven in phase.

The outcome being that the pattern at that frequency is approximately the same as if equal length feedline branches were used.

Referring now to the right hand one:

I suggest that the figure is in error because the scenario is not ALWAYS wrong.

My contention is that at a single frequency, that where the low loss feedline to one DE is an integral number of electrical full waves longer than to the other, the Yagis are driven in phase.

The outcome being that the pattern at that frequency is approximately the same as if equal length feedline branches were used.

Note that I am not trying to excite a purist discussion about branch vs distributed feed arrangements for phased arrays.

Am I on the wrong track?

Owen

I see nothing in that diagram that describes the physical/electrical
spacing _between_ the driven elements.

It is discussed elsewhere in Gordon's paper, but it is not directly relevant to the question that I posed.

In fairness, Gordon did say: "Departures from these rules are possible
for special applications outside the scope of this discussion." The
exceptions identified above would be exactly what he had in mind.

Reversed connections and/or unequal feeder lengths certainly can be
used, but they are advanced techniques requiring clear intent and
careful engineering. In all other cases they will be "WRONG" as Gordon
says.

Yes, he does make that statement. I focussed on the diagram.

I guess his "WRONG!" means "possibly wrong (see text)".

>
> Reversed connections and/or unequal feeder lengths certainly can be
> used, but they are advanced techniques requiring clear intent and
> careful engineering. In all other cases they will be "WRONG" as Gordon
> says.

I received comment on my antenna described at
http://www.vk1od.net/4over4/ as follows: 'It "doesn't" work because you
have inserted a half-wave time delay in the feed to one antenna (in your
case it appears to be the upper antenna) which tilts the beam up or down
a bit (in your antenna, it will tilt upwards)' and in following
discussion it is asserted that although the feed to one antenna is
transposed, it does not correct the additional half wave phase shift of
the longer branch.

Gordon's paper was offered as support for that position.

I think my design is sound, the rationale is set out in the article. I am
a little flattered if it is considered an advanced technique, but it
seems to me fairly elementary.

Actually, since posting the original article, I followed up on Gordon's
reference to the ARRL Antenna Handbook. It has a diagram that shows
pretty much what I did, it is (c) at http://www.vk1od.net/lost/Fig7.png .
(The difference in my case is that the stacking distance was chosen for
optimal pattern by trial and error with an NEC model, and the coax has a
velocity factor around 0.82.)

[snip]

Richard, hey, clearly you have never met me in person. In person I am even more persuasive than in my often
ill prepared USENET postings, it has been my experience that the ladies NEVER SAY NO to me!

Heh, heh...

I was an only son, raised in a large family of sisters by my mother who was often alone since my father was a seagoing
sailor. And so... at a very early age I learned to "convince" the ladies of the veracity of my assertions and requests.

Long since grown into a man, I'll turn 67 next week, I have polished my approach to the point that the ladies always
accept everything I say. Heh, heh... Whenever I ask the ladies a question or state an assertion in my own inimitiable way their
responses are always along the lines of...

"I'll bet you say that to all the ladies" and they invariably end with,
"sure you may, it would be my pleasure, you are such a smooth talker".
[grin]

Smooth talker, sweet talker, what ever works, I say!

On that particular subject there was a "cute" but interesting, entertaining and amusing two page piece in last month's Esquire magazine
entitled something like, "The Smooth Talker" or "How to be a Smooth Talker". It was really quite an amusing piece, and apropos to
the current thread.

If you don't get Esquire take the time to look up that piece at your local library, I'm sure that you will get a laugh or two, I did.

OK, enough of this 'aside', let's get back to the real technical discussion at hand.

None of the guru's lurking around this particular newsgroup (r.r.a.a) will deny that whenever electrical charge is "jerked" that photons are emitted. And... none of the gurus hanging hereabouts will deny that photons can have 'spin'.

The only question remaining is that of the relative quantities of left and right hand 'spin' of photons in any specific situation where photons have been 'jerked' lose from the electrical charge and whether the 'spin' is quantized or continuous.

Comments, thoughts?

-- Pete K1PO
-- Indialantic By-the-Sea, FL

PS: Gosh, I've missed this group.... Cecil is fine, but it's just not been the same since dear Reggie passed. I miss Reg, especially at this time of year. At least one could easily understand the King's English as written by dear Reg, and Cecil's English is not that bad for an "Aggie", but Richard, since your purple prose takes English expression to a completely different level, you certainly help keep this group entertained. Thanks for what you do for us all!

Your version of the 4/4 is phased correctly as shown. The extra
electrical half-wave compensates for the gamma match being on the
opposite side, as both are equivalent to a 180deg phase shift.

Gordon's paper does not deal with situations where the use of different
lengths of feedline is deliberate.

>I think my design is sound, the rationale is set out in the article. I

It cannot be done without *first* knowing how to make two lengths of
feedline exactly equal, so that's got to be "more advanced"... er,
right?

Dave:

[snip]
> Do you have any hobbies?
[snip]

Technical hobbies, or social hobbies?

Other than kibitzing on r.r.a.a?

Would you believe that I'm a salsa dancing champion? Actually my wife Kathy (who is a dance genius) and I do a lot of dancing which might be described as a "hobby" of sorts.

Let me tell you about one of our recent dance escapades.

About three weeks ago my wife and I were in Paris, France, returning from three weeks in Italy where, among other things, we hiked to the top of Vesuvius. But that's another story!

All this to say that we stopped over for a night in Paris on our way back to Indialantic from Naples. We took the opportunity to take in dinner and a show at the celebrated Moulin Rouge near Pigalle in Paris.

Ouch! That was an expensive evening! It didn't look too bad in Euros, but when the bill showed up on my Visa statement in US$ it was heart stopping!

Front row seats at the Moulin Rouge, right up against that venerable125 year old stage, and the multi-course meal with a magnum of champagne was great and as you will note from the rest of my "story" it turned out to be a memorable evening!

Kathy and I took the train from CDG airport into the Gare du Nord, and then we took the Paris Metro over to the Pigalle station leaving time to get lost at least three times before we got there. Pigalle as you know is in the center of the "red light district" of Paris. The Moulin Rouge is in the middle of that district on Monmatre, the dandy's, Princes and Princesses do not walk along Pigalle to get to the Moulin Rouge like Kathy and I did, rather they arrive right in front of the door in long black Mercedes limousines.

Well... at the Moulin Rouge they serve a first class dinner before the show if you elect to take the dinner and show rather than just the show.

During dinner, a small elegant music ensemble is fronted by a talented duet of singers, who are sort of the Parisian equivalent of
Edye Gorme and Steve Lawrence, except they sing in French, such songs as "Chanson d'Amour", etc. as enteratinment for the diners.

During dinner that part of the main stage that later becomes elevated during the main show is kept at ground level so that people can dance if they wish, during dinner, and before the main show.

The Moulin Rouge was packed the night we were there and, as usual whenever there are lots of "observers", there were not many dancers on the floor! Only a couple of pairs, who had consumed all of their champagne by that time got up to dance staggered through a few 'slow dance' steps, and so the floor of the Moulin Rouge looked downright barren.

My wife Kathy suggested that WE get up and dance. As a dance instructor, you can well imagine that Kathy is not shy about that kind of thing. My athy always likes
to be the first one out on the dance floor.

Well the small ensemble and the two singers got round to a number with a certain beat (NC2S) that my wife and
I like and so Kathy suggested that we get up on the Moulin Rouge dance floor in front of the whole audience that night
and do the Night Club Two Step.

Now for those of you who don't know, the NC2S is a modern dance that was "invented" by and American,
Buddy Schwimmer of Costa Mesa, CA a few years ago. NC2S is a very elegant dance done to slower music and is very elegant and quite
unique.

Aside: NC2S is known in the USA but likely not well known in Europe. In case you are not a dancer, you should know that Buddy Schwimmer
happens to be the father of Benji Schwimmer who won the "So You Think You Can Dance" show two years ago, and he is also the father of Lacey
Schwimmer who was partnered with Lance Bass on the "Dancing with the Stars" show this past fall. Lacey and Lance
came in second on the show this year, after that graceful "Brooke Burke" and her partner Derek Hough.

And so... "there we were", my wife Kathy and I dancing the elegant Night Club Two Step all alone on the dance floor of the Moulin
Rouge in Paris, in front of an International audience of several hundred people.

Well... we were surprised! As we danced together to that beautiful slow and sexy music, all of the dinner "chatter" stopped and all eyes
in that famous 125 year old theatre, were on us as I showcased Kathy's wonderful dance skills (as the dance partner/leader).

The highlight came as the music ended and we walked back to our dinner table.

The audience at the Moulin Rouge favored us with a standing ovation!

Apparently they had never seen the Night Club Two Step before!

Unfortunately no one recorded the happenings at the Moulin Rouge that night, but... for those of you who might be interested to see what the NC2S looks

like
as it is danced, you see an example on You Tube, just click on...

http://www.youtube.com/watch?v=VoyxrEbZpSw

BTW... the Moulin Rouge show after dinner and dancing was spectacular and well worth the $$$$$.

I suppose that if it were not a 125 year old tradition in Paris that the Moulin Rouge show mighty be described by Americans as a "high end" Las Vegas show,
except that... Las Vegas, NV was not even in existence when the Moulin Rouge started its run 125 years ago!

I'd say that one should really describe Las Vegas shows as pale imitations of the Moulin Rouge show! [smile]

Guys who are reading this will be pleased to know that not only is the whole show spectacular, but the show girls at Moulin Rouge are spectacular as well.

All this to say, Dave.... yes I do have hobbies!

And... I am often "asked to dance"...

BTW.... I highly recommed dance to any man/boy who wants to be closely asociated with women!

Dave, I'd challenge you to name a hobby for a man that is as exciting as a hobby where the man gets to hold attractive girls in his arms and run his hands all over thier bodies for 3-5 minutes at a time and the girls thank him when it's over and asks him if they could do it again soon?

Ciao!

Was teamster in a previous life (well, a younger one), I have nothing
bad to say of unions. I can remember stopping by the pub and being
given a "bad time" by non-union workers in my industry. I started more
than one fight by simply telling them, "I work for over two times as
much as you. I have complete medical, dental and prescriptions. My
retirement goes into a fund which is g-u-a-r-a-n-t-e-e-d. I don't sweat
a few bucks in union dues." -- For some reason, that was all it took!

At the risk of being so identified with that villified group, I will
deny that statement (for what it is worth).

>And... none of the gurus hanging hereabouts will deny that photons can have
>'spin'.

That is a fairly short list of what is "not" denied. Why don't you go
further like Gurus refuse to deny:
1. They hate their parents;
2. They stopped beating their wives;
3. The earth is perfectly round;
4. Gussian arrays are the perfect metaphor for radiation;
...
n. and on and on and -heh heh- on.

You wanted a tone detector. Then you asked if a vibrating reed
(mechanical resonator) can be one. Then you said that there was not

many methods, so i named some that even did more complex things. You asked for the discussion and received it.
Moreover, the tone squelch system does some other complex things as well. Particularly when multiple users (groups) are on a single channel in a single locale.

In order for a union to work, there has to be money there that you can
squeeze out of the company. And you have to have a bargaining position. If
what you do prevents the company from having working capital or market
changes force the company into bankruptcy, where is your bargaining
position? If the company and it's industry is indeed viable, go for it.
Corporations have unions but they call them cartels. There has to be a
struggle against the causes of exploitation. You don't want to see
situations like two-tier for employees or CTA voting pay cuts across the
board so they don't lose members who pay dues. Even though they have
hostages. My dad was a teamster for several years, but the pay stunk anyway
so he went to insurance sales during a strike so we wouldn't have to live on

macaroni and cheese. I never cross picket lines, I buy American made products only or go to the thrift store. OK, I admit it I have bought new stuff made in China probably by slave or prison labor because you can't even get some products that are American made anymore. I drive an American car. This is where it all breaks down, because if you are fighting to get food on the table and decent wages, there are 10,000 more going out and buying products made with slave labor and doing volunteer work while living on pensions. If UAW can't get dues, who will guarantee the pensions? Ponzi?

My other peeve is tons of money out of the retirement fund (PERS) to the Dems, who have so many other agendas that they conflict. Like selling out to Chi-comms. They got kicked out of Washington and Oregon, so the Dems shut down and leased them Long Beach Naval Shipyard to bring in Megatons of cheap crap into the country. Like gun control. Remember Matewan.
Abortion. Any one who is OK with taking away peoples Constitutional rights and killing people who don't have a voice might not care about you or me either. And what's with this gay crap. If people want to do stuff like that, I certainly don't want it forced on me or my kids.

The Fannie May/Freddie Mac bad loans were guaranteed and forced on the banks by gov't. mandate and Barney Frank has been saying since 2004 that there was nothing wrong, even while another Dem was saying it was the regulator's fault for allowing it (ie we need more cops). I guess that makes Barney some kind of expert.
http://www.youtube.com/watch?v=_MGT_cSi7Rs&NR=1
BTW there is a lot of this pro and con in related YouTubes.

Nothing wrong with having a heart, you gotta care about the consequences though. And fighting greed with greed gets you more greed.

As I implied in my previous post, it can be hard to convince people that they need to responsible and realize that the only way they can get what they want, need and be prepared for illness and old age, is with their own hands and job (or, start their own business) ... there still exists the myth that they can work for cheap with no benefits or retirement, GUARANTEED, funds and it "will all just work out", or "someone will provide for them."

If you are working for a company, or in your own business or contracting and the result is less than satisfactory, quit and go elsewhere. The crash of the stock market and the future coming times shows the folly of a "positive attitude", based on irrational grounds.

There seems to be a "myth" going around that "it will all just work out." And, one can work at a poverty wage and "get ahead."

Like I pointed out, many are ready to fight rather than come to their senses. My wifes parents worked hard their whole lives. Somehow they were sold the dream that all it took was hard work and they would be rewarded--they now are attempting to exist on social security, needless to say, it ain't workin'! If my father-in-law was a retired UAW worker, he would have a much different story!

It is fine all these companies run about not providing well for their workers--but, just let them pay the welfare-funds/medical/drug/etc. needs of their workers in their old age--NOT ME, my family, or my friends!

Regards,
JS

[snip]

Your denial is not worth to much simply because, as The Bard had one of his
thespian protagonists quote,
"methinks he doth protest too much".

And, so... well, I am afraid to admit that... I don't really know which of
the honored denziens of this
group (r.r.a.a) are the select members of the secret clique of lurkers known
as "The Gurus".

It seems from what you have written above that you deny being one of The
Gurus.

I believe it was Groucho Marx who said, "I wouldn't want to be a member of
any club that would accept
me as a member", and so...

Me?

Hmmm... I not only deny membership in The Gurus, but I actually know that I
am not a member.

Now, if my recollection is correct, Reg Edwards may have known the names on
that secretive list of gurus, but
since Reg has now passed to his reward and, although we have evidence of
Reg's own electromagnetic expertise
in the form of the many programs and web site information he graciously left
for us gratis, there is no evidence
that Reg ever belonged to The Gurus. In fact, I recall Reg indirectly
denying his own membership on many
occasions by referring difficult and sometimes rhetorical questions to "The
Gurus", often answering those
questions himself after much newsgroup discussion.

Apparently Art Unwin has definite knowledge of who The Gurus are, since he often challenges and castigates
them at the same time. Unfortunately Art would condemn the poor IEEE because of corrupt behavior, and
so I am not sure that Art is really connected in the electromagnetic world.

All this musing to note that... USENET is a great tool for scientific discussion, that adheres to the most basic
tennets of "The Scientific Method".

Why, anyone... from freely identified persons, to anonymous posters, may make whatever assertions and pose
whatever theories they care to, and everyone knows that eventually the truth will be revealed as those assertions
are examined in the brilliant light of the scientific cross examination that occurs in these r.r.a.a threads!

Hey! Where's Art when you need him? Art... I've created your opening, now its your turn...

It's saturday night and I gotta go dancing, the girls are waiting... :-)

Peter, there are no gurus on this newsgroup period
When I extended the Gaussian law of statics by making it a dynamic
field
I proved beyond doubt that radiation was via particles and not waves.
David and others denied that you could even bring in the subject of
statics
when discussing radiation even tho it is known that the force between
particles
is part and parcel of Maxwells laws. I might add that many joined him
in this thinking
like lemings. Since that time all of this group have sunk lower and
lower with respect to radio.
All have demanded a definition of equilibrium no less so all are
lacking in science.
They have all denied that mathematically my extension of Gauss results
in the same mathematics
that were arrived at by Maxwell. When I point out that eddy current

(really a field) is the weak
force that Einstein was looking for as he was convinced that
radiation held the clue he was looking for.
Yup they howled at that one too. Ofcourse it was Maxwell who found out
that one of the existing laws by the masters
was not in equilibrium which he then corrected by adding the
displacement current which describes the
action of the eddy current field in lifting and applying spin to a
charged particle. Howls again from all
as this could not be found in any books. Ofcourse this operation in a
macro scale is used daily in scrap
yards for sorting out materials as well as non destructive testing but
again the howls rose again.
So I then told them that maxwell based computor programs account for
all the forces used in radiation
which they could find out for themselves with a optimizer program as
long as the input was not slanted towards a planar design so that it
may be discarded
But then they are self perceived gurus thus don't need to use a
computer as all is already known, ala their books that are more than
50 years old.
I then informed them that one naval base had tipped all their
verticles for better performance by incorporating the weak fork which
also can be confirmed using Maxwells laws. Now I am being considered
and idiot no less. So I then posed the question as to where the
current goes when reaching the top
of a fractional wave antenna and the answers I got was that a closed
circuit is not required for radiation. And this thinking goes on and
on but at no time
has anybody come forward to refute my analysis in anyway, mathematics,
computor programs or what ever.
This whole story reminds me of the Yagi invention that was dismissed
totally by the Japanese intelligensia but embrace by the rest of the
world such that the Japanese never used the Yagi design thru out the
length of the war which was their loss. Peter, all of the above has
been pointed out to this group of self perceived gurus over the past
few years but all has been denied as it is no where in the books to be
read.
When I joined this group more than a decade ago Roy W7EL said he was
going to expose all the old wives tales that floated around including
all the newly touted sciences that were being tossed around but his
silence has been defining while at the same time Snakespere has been
prancing around in his fishnet pants while talking in tongues. Ian is
still demon strating how to solder a connector on coax while the Naval
instructor Woods in Washington
is in total belief that the US navy is using tilted antennas for
superior performance. No Peter, there are no gurus on this newsgroup
as I have one time or another proved that they are nothing more than
talking heads beyond doubt.
As an aside Peter on another subject I have no bone to pick with the

professional societies only the Universities for giving away
information provided by tax payers money and thus was not theirs to
remove from publics eyes
Best regards
Art Unwin.......KB9MZ.......xg (uk)

John, some years back the Government aproved the removal of a
percentage of pensioin funds
for their own use as long as the pensions were not in jeopody. In
other words if the funds earned more money than expected
then the company could use that money. So the majority of pension
funds were kept at the prescibed minimum level.
Now pension funds have turned south and the businesses have also
turned south such that they cannot replace the funds removed.

This little pot has started to simmer but has yet to get to the
boiling point. As Yogi Bear said i9t aint over until it is over!
Everything was OK when we let the market decide but then greed changed
the metric of the market.

Hi Owen

Richard Clark once told me how to combine 4 antennas in an array. He got me to feed 4 antennas, 50 ohms each with 50 ohm coax with no dividers. I just fed each antenna with 50 ohm coax. At the point where the 4 coaxes get combined, I connected two coaxes in series and the other two also in series. Then parallel them to get back to 50 ohms. The result is two 50 ohm loads in series to make 100 ohms and with the other 100 ohms in parallel, the combination is a good 50 ohm load. You can see a sketch in the Feb 2008 QST. It works pretty slick when the antennas are 50 or 70 ohms where it is easy to get the right coax impedance.

I've administered business band radio systems. CTCSS is similar to a 3
tumbler keylock.

Actually, that is false ... you could not prove such a thing, unless you
force us to disbelieve our own eyes! To proceed claiming such is only
to invite us to think you daft!

http://www.newscientist.com/article/dn14172?DCMP=ILC-hmts&nsref=news1_head_dn14172

The best you can now argue is that light is composed of a type(s) of
particle(s) which travels as a wave(s); And, still, it seems to possess
both qualities--i.e., behaving both as particles AND waves ... but then,
we already knew that.

YES! Indeed, it is much worse than that, the gov't has also used SSI funds by "tossing them into "general funds", questionable-investing-of-these-funds, etc." Now, they attempt to "resell" us our SSI with increased taxes and "increased fees." (just another name for "tax(s.)")

Ever notice how they end up taking library and other public service funds, tossing 'em into a general fund, then reselling us the services, again-and-again-and-again-... well, most DON'T seem to! I just brought this up at a board of supes meeting in my city, and was threated with removal from the room ... (well, I did get a bit "hot", seems hot enough to get a few others to take a verbal stance) Anyway, we convinced "them" NOT to shorten library hours--at least.

It is time for investigative reporting, FBI/congressional investigations and criminal proceedings against the guilty parties.

Instead, we are getting "bailouts" which reward the very crooks and powers-which-be which are responsible for this fine mess! And, NOT one word of closing the "loopholes." (DEFINITION: loophole = sanctioned criminal activity!)

Hi Owen

I dont know how to include pictures in this text.

I would draw two touching circles to represent the outer conductors. The
generator is fed between to the inner conductors. Hence, two 50 ohm loads
on the coaxes will look like a 100 ohm load to the generator.

Jerry

Ok, I understand, you the two inner conductors with a 100 ohm load
between them.

You have another pair like that from the other two arrays.

How do you connect them to the main feedline.

Owen

Hi Owen

The two 100 ohm loads in parallel give a 50 ohm load to the 50 ohm coax
main feed line. I used a ferrite "balun" where the unbalanced 50 ohm
main feed line connects to the center conductors that are connected to be
a 50 ohm load. .

John I am confident about my analysis. Scientists have not been able
to explain
anything in radio that procedes at the or near the speed of light or
explain how communication is resolved.
I have provided an explanation that is duplicated in many ways every
day and vindicated by Maxwells equations.
Reviewing the URL you supplied. The photograph is not a simple proof
that it appears to be. Camera pictures are notorious
in fooling people into falible interpretatations. However you can
believe what you want. I would point out that I have melded many
things and aproaches
such that all mesh in a single conclusion None of these separate
aproaches have had any errors pointed out whether it be mathematics or
otherwise.
I am not a programmer so there is no way I could have injected such a
complicated scenario into all the programs now available. Nor could I
have invented the weak force that Einstein was convinced resided in
the analysis of radiation. On the other hand there are many
photographs available of the Lock Ness monster, alien space craft and
alabaster statues with tears coming from the eyes. By the way, compare

different aproaches of resolving radiation analysis and check which form provides the minimum losses and you will find that planar antennas just don't measure up versus antennas in equilibrium. On the other hand if the field of an eddy current is not the weak force that Einstein forcast or predicted then where and what is this force that propels a wave, presumably without spin that knocks out what I have suggested? At the same time does it fit exactgly the jigsaw pussle that Maxwell left us with the puzzle turned over so the picture could not be pre determined? And as a finale I see particles occilating possibly in tandem form that gives the impression that the particles arenot interconnected in string form but a series of interactions between particles that operate in their own right als
H2O in molecular but unbound form as with mass
Best regards..... good effort but no cigar. I would aim for best results at the computer programs or finding the true weak force, or determining how a electrical wave travels with intelligence or the center of all proove that the mathematics as applied to gaussian boundary that is made dynamic under a time varying field DOES NOT equate with the mathematical laws of Maxwell and last of all that the term equilibrium has NO PLACE in the laws devised by the masters with respect to the Universe. I left out the part that a radiater must be straight as expoused by some pseudo experts in the radio field as well as to how the addition that Maxwells made to his laws provide the mathematics for the tilting action on a radiator for minimum lossand the many other things I have pointed out
My very best regards and best wishes in any endeavor that you wish to undertake in an effort to proove me in error. There will be some talking in tongues by the group but I am absolutely positive there will be no fresh revalations other than just words provided over the years which have meant nothing
other than the intent to hurt. Goodnight
Art Unwin KB9MZ.....XG....(UK)

You didn't mention the balun in your fist posting. Without an effective balun, the system would be quite poor.

In each pair of antenna side coax lines where the shields are tied together and the inners are used for a 100 ohm connection point, you drive one coax in opposite phase to the other. Your description did not note that there is particular phasing requirement for the coax lines to the antennas, and polarity of connection of the DEs.

BTW, you have constructed a type of power divider. There are a lot of different ways to do it.

Owen

Well, that is simple enough then. You are to have us disbelieve our own
eyes ... good enough, we have that cleared up.

Regards,
JS

John you can interprete what you want. For me I will await for
somebody
to prove me wrong in the many areas that I have espoused and allow
those that
just want to make nasty remarks go ahead with their agenda. Sooner or
later reason will prevail
and Snakesphere talking in tongues will fade away.. I look forward to
the time that a real guru on radiation
appears on the group to discuss what is salient to the subject
Very best regards
Art Unwin.......KB9MZ........xg (uk)

Now, we approach that time of risking way too much verbiage on way too little.

Yes, I do trust my eyes. The research done to get that picture was done by a university; I don't believe the lady, who was head, was out to reinforce any preconceived ideas/theories. And, I don't believe New Scientist is a nutter-rag-on-the-fringe; It does push-the-evelope.

THAT is my interpretation; I fear it the only one possible, at this time. Light and, most-probably, EM (no picture, yet) behaves with properties BOTH resembling particles and waves. (Thank gawd, at least something gives us valid reason for argument!)

You can wait for the cows-to-come-home; that research stands; the picture is NOT a fraud--IMHO. I have no reason to "be nasty"; I simply believe it to be as it appears ...

I am at a loss for what Shakespeares' stance would be; As you say, may reason prevail.

My very definition of the meaning of "guru" is "clueless" (in the context which I have used the word here); Now, you wish to wait for one of "them?" <scratches-head>

Salient? Change that to logical and I will "look forward" with you ... now, please, don't "be nasty" ... end-of-story.

Regards,
JS

Hi - I am trying to play around with modeling a loaded 40 meter cubical quad. To start I made a single loop the size I wanted (about 2/3 full size) - I then looked at the impedance on 7.1Mhz. I added a load (inductance) to bring the loop to resonance on 7.1Mhz. I then created some parasitic elements - a director and reflector. I used the same value load for these elements. Now, can I just adjust the lengths of the wires to tune the feedpoint impedance and directivity and leave the value of the load alone? Or is there some reason I will need to adjust those values too? I placed the load opposite the feedpoint, FYI.

Shakespeare will have little to say about it. The term "speaking in
tongues" comes from the New Testament:
<http://www.bible.org/page.php?page_id=393>

Also, reason has rarely prevailed. It's usually rationalization,
seduction, politix, or main force that carries the argument. None of
these show any indication of fading away.

How I create circular polarization or simulate a rotating antenna
direction finder. Pretend I'm holding an antenna:
<http://www.LearnByDestroying.com/panorama/jeffl.htm>
When it's done loading, move the mouse around the picture.

Sorry, but the messiah is busy trying to save the multitudes from,
moral debauchery, religious damnation, economic meltdown, global
warming, and the evil oil cartels. Antenna design and theory will
have to wait until all the other evils are dealt with.

Also, guru means "teacher". There are several current and former
teachers that post high quality answers here fairly regularly. If all
you want is a guru, they're readily available. All you have to do is
read, listen, and understand.

the simpler way is to just parallel all 4 of the 50 ohm loads which gives
you a 12 ohm load at the common point, then parallel 2 pieces of 50 ohm coax
1/4 wave long to form a 25 ohm matching section, that will get you back to a
50 ohm common point with no need for a balun.

Hi Scott, Seems to me since this is a quad that your goal is maximum gain or F/B. As such, I would adjust the loads and element spacing keeping the element lengths constant, until you have the current distribution in the elements optimum for your goal. Then check the source impedance, and if it is not too bad, devise a way to match. Suggest that instead of a single load opposite the source, use two loads, should help with current distribution. Good luck.

... why? It's a way it's done for broadcasting antennas. There's little
reason why the screen of the feeder can run continuously into the screens of
the transformer sections and on into the screens of the cables that feed the
individual Yagis. If the drive-points of the Yagis are equipped with
adequate baluns then there should be no more common-mode current on the
outside of the continuous screen than for the case of a single Yagi.

Chris

It still all goes back to accountability. The majority of voters have turned into children and allowed these things to flourish. The stupidest people are the ones who sign petitions at grocery stores. No time to read it or even evaluate the claims. Even the press that we all thought would be a vanguard of freedom have turned into shills or are yes men (women) who say it is OK to report on "what somebody said" even if it's a crock.

I have been to city council meetings too. Not long ago the idiots outvoted the only sane one of em to "get in on" a abandon vehicle abatement tax of $1 on the vehicle license fees of which 50 cents would go back to the city. When they found there were further requirements to get the money, they wound up passing new ordinances to prohibit storage of vehicles in the driveway or on your own property so that they could tow away enough vehicles for carbon credits or some such nonsense. Since then I have vowed to vote no on any legislation that isn't concise.

Another definition of loophole: The product of deceptive legislation that through obfuscation, nullifies itself so that it may be perceived as "doing good" while opponents are vilified.

Pete Said,
"Circular polarization describes the condition when an electromagnetic
wave
is spinning or rotating with around its direction of transmission.
That is
the electric vector (E) of a circularly polarized electromagnetic wave
is
rotating with an angular velocity as the wave travels through space.
This
is in contrast to the E vector of a linearly polarized wave which
merely
oscillates in one linear direction."

Pete, I believe this is your error in thinking,instead of a a
spinning field perhaps it would be better just to few it as a coil
moving towards you with no rotation.

In the old days it was commonly thought that a mirror image of an
assailant was in the eyes of the dead
This ofcourse is not true since the eye does not see what the brain
interpretes what they see.
A pair of glasses was made that inverted the image of what apparently
seen by the wearer, such
that other people was seen as being upside down. Within a day the
brain correctly interprets the inversion and from then on the wearer
saw people in an upright position even tho he was wearing glasses that
inverted the vision.
This brings home the point that the brain sees an image in some form
based on electrical pulses recieved from the eye and with its
inherrent brain power interpretes what is seen in term as to what it
should be seeing.
Thus seeing is just a reflection of what the brain states you should
be seeing based on past experiences.
So... seeing is not believing!
Regards
Art

Jim, are you introducing another scheme, or were you trying to explain Jerry's scheme. We sorted Jerry's scheme, he just overlooked some vital details in his first description. (I haven't said it to date, but I dislike Jerry's scheme, principally over its use of the balun.)

Yours is another scheme.

There are a lot of ways to do it.

The original question was over an article's diagram that stated that unequal lines are "WRONG!".

Yours and Jerry's responses have not dealt with the original posting, but if anything offered alternatives that might be seen to suggest the original configuration is flawed.

Owen

Yes, we already had that out, didn't we? You would have us NOT to believe our eyes (actually, scientific experiment/observation with the aid of visual rendering devices and very short bursts of light.)

And, you do seem to be suppling proof of what you claim, "... inherrent brain power interpretes what is seen in term as to what it should be seeing." Or, in other words, "defective functioning by the processor--i.e., "the brain", is non-productive. Or, simply put, you see what most would consider proof, as fraud ... interesting, but you have demonstrated this previously ... and, there are indeed conspiracies--however, I don't gage this to be one of them; And, I am suspicious, yanno'?

And, your statement, "In the old days it was commonly thought that a mirror image of an assailant was in the eyes of the dead ..." would now be known as, "The memory of past visions, at least some of them, remain recorded on the brains "hardware" until erased by decay/degradation." But, you either fail or attempt to hide, "they" had it right; It is NOT unfathomable that these images may one day be viewed for some purpose (find a murderer, etc.) Yeah, they made a lucky guess ...

Now, I warned you, to pursue your present path invites us to think you daft. However, I was wrong; Rather, it is now approaching the point where you demand we think you daft! If there is purpose here, like leading us "down the path" to a BIG WHAMMIE (or, in other words, a point where an undeniable truth lies at the bottom and so, causes us to re-think what we think we know)--then get on with it, my attention span grows short ...

When there are errors in the logic which you attempt to use as supporting evidence/proof/parable to prove yet another point, of yours, which has been found to be in error--you do yourself NO favors. :-(

Once again, we have reached the end-of-another-story. But then, no one enjoys a surprise more than me, go ahead--if you can.

Regards,
JS

Is this a quiz?

I simply questioned your statement that the very common arrangement of star-point and transformer, implemented in co-axial line, should be 'a common mode nightmare' as you put it. The middle portion of the diagram (http://www.vk1od.net:80/lost/Fig6.png) posted at the beginning of this thread shows baluns on the drive points of the dipoles and nowadays Yagi antennas for amateur as well as professional use appear to be sold more often with integral baluns. Co-axial feeders always interact to some extent on account of their outer conductors being in the vicinity of the antenna(s) but there are simple steps that can be taken to minimise this.

However, I concede there may be some reason to want to combine/power-split using balanced line but ultimately it will need to be connected to a co-axial line - if the intention is to achieve this without use of a balun then I wonder if this would be more of a 'nightmare'.

Chris

Two colocated matched antennas 90 degrees apart electrically, one at a
right angle to the other, will make very nice CP.

It will be much easier to make the two elements exactly the same
in terms of wire lengths, and just increase the load for the
reflector element.

It must be a quiz - when I point out that Dave does not call out for
isolation (*ferrite* BalUns as have been identified through Jerry's
and Owen's correspondence) and as you do as an aside - then what is it
that you find debatable about my commonplace observation?

Common Mode doesn't disappear into the VHF/UHF. Common Mode creates a
complex impedance product that is generally unaccounted for (ignored),
and would certainly disturb phase relationships where phase
relationships are of primary importance.

The only other alternative is consuming transmission line in coils to
the same purpose. That hasn't been offered as a choice until now.

Hi Owen,

This illustration seems to serve other commentary as it is filled with odd eccentricities that are not very germane to the issue you raise below. Eccentricities aside for the moment, I have to make a lot of presumptions about an odd arrangement of 12 radiators. Some of them are symmetrical by groups, but not all of them are symmetrical in toto. I presume the groups are significant; but initially, what they are significant of escapes me.

The + and - markings in the top tier four group, along with the commentary, is suggestive; and I have to supply experience in the matter to know that not ALL +s are connected together (and neither are all -s connected together). I presume this top tier is a 4-Bay, but there is nothing to support this except the graphical allusion.

Also from experience, I would presume that connections are not horizontally placed, nor diagonally. The impression of incompleteness is accruing.

>I have highlighted two of the diagrams with a yellow background, and seek
>opinions on them.

This implies (by your statement of "two" diagrams) that along this middle tier of radiators, we have broken away from what might be a 4-Bay; and we are examining three pairs as choices put to an unstated problem. Here, the eccentricity of what looks like an appendix hanging from the folded element is further disturbed by what I can only imagine to be an abstraction for a coax feedline. Incompleteness is compounding.

If I am to pursue my forced presumptions, I would have to say that this middle tier lacks many more alternatives in connections and length variations. Incompleteness has reached saturation - which is what I think you are responding to.

>same as if equal length feedline branches were used.

Well, the original author does neglect to specify length, leaving it
to the reader's imagination to "presume" (have to say it) equal feed
lengths judged by eye. Unfortunately, the third example explicitly
offers this option, but only to those connections where phasing dots
are matched. Like I said, there are many missing alternatives.

Your imposition of an extra half wavelength in one feed may be
technically accurate, but it fights with the importance of their
length - which is to be found in the lost commentary, no doubt. I can
well guess, but that same commentary may illuminate these limited
choices and explain the eccentricities. I wouldn't want to slog
through that commentary, however.

>Referring now to the right hand one:

This would be a stretch of the imagination where application has
fallen into the ditch to serve argument. If the lengths drive
frequency to match to cable proportions in wavelength that do not
serve their loads, then such solutions are hardly useful.

> I am wondering why you are trying to resurrect this train wreck.

I was seeking comment on the issue of asymetric branch feed topology.

It was put to me that accounting for the phase shift due to the different branch lengths does not fully account for the time lag. My contention is that in transforming the problem to the frequency domain, conversion of time lag to phase lag fully and properly accounts for the different branch lengths.

Gordon's paper was offered as evidence that my feed was "WRONG!".

Yesterday, I note that Kraus has a clear diagram of branch vs distributed feed, and the technique of transposition to offset a half wave phase delay.

I also note the ARRL agrees with me (http://www.vk1od.net/lost/Fig7.png (c)), but that isn't a bullet proof recommendation!

I am now confident my critic was wrong.

Owen

Hi Owen,

That seemed to be a strain based on the illustration offered as it
wanders the field.

>It was put to me that accounting for the phase shift due to the different
>branch lengths does not fully account for the time lag. My contention is
>that in transforming the problem to the frequency domain, conversion of

Too many conversions going on there in your statement. I don't see
any transformation (conversion?) to OR from the frequency domain; and
I don't see what that would offer. Distance, "polarity," phase and
time are all hands on the same watch. Their conversion is trivial -
as you appear to be rebutting to your critic.

>Gordon's paper was offered as evidence that my feed was "WRONG!".

The offeror left it you to sort it out rather than arguing their own
case, hmm?

True.

>I am now confident my critic was wrong.

If the criticism is, as you offer above about accounting for "time
lag," as if that fell into some special category, then your confidence
is well grounded.

When I examine your other correspondence to piece together the story,
then both sides of the argument have valid points. Yours, being more

general, is more conclusive.

The second take-home here seems to be, if you wish to teach someone how to perform a task, or build a project, you shouldn't do it with negative examples without being encyclopedic to completion (which invites boredom).

A proof with the free version of EZNEC was easily achieved with some minor elaborations for the NBS Yagi. That is the beauty of modeling, it encompasses ALL the ways to fail or succeed.

OK, for modelling purposes, you can keep the load constant, and vary the element lengths. From a practical standpoint, if you have this beast up in the air, tuning is easier with a tapped inductor.

Other factors that will effect the gain and F/B are the element spacing, and how high you can get the thing. Practically, these are not things you can change easily.

I just did a quick 2 element 66% (reflector) quad in a diamond configuration with 17' spacing on EZNEC, and got a 10.25 dbi gain at 35 degrees. F/B about 13 db. Feedpoint impedance was 44+j0 with a 678pf shunt capacitor. The element lengths were the same on both, varied loads to get max gain and best match. The center of the diamond was 50' up.

Hi Richard

What is the reasoning used to indicate 300 ohm line is used in (B) of the referenced http://www.vk1od.net/lost/Fig7.png .?

Hi Jerry,

It should follow the rule of being the square root of the product of
the source and load Z.

Hi Richard

OK, on the geometric mean, but, the author surely realized *that*. I got the feeling that I was missing something of value when it wasnt obvious to me why 300 ohm line was used.

The figure is is from the ARRL Antenna Handbook.

In (b), the numbers are rounded. A nominal 280 ohm dipole via 1/4 wave of
400 ohm line gives 570 ohms at the tee. Two such branches are paralleled
for 285 ohms, which on 300 ohm main feed line line results in a VSWR of
1.05... should be acceptable.

Does that help?

Owen

Richard,

That same thought occurred to me on first reading it. Teaching what not to do has its place, but it 'dumbs down' the learner.

Explaining the concepts, and how to use them imparts empowering knowledge more than rote learning of negative Rules of Thumb.

Still, people keep telling me that that is all old world thinking, today you train (instead of educate) people to specific and narrow tasks, and competency for immediate tasks (train to the need) is more important than knowledge of principles and concepts.

I have quals to opearate a fork lift. One of the questions I was asked for assessment was "name six places that you should not park a fork lift". Of course, one cannot just nominate any 6 places that would be inappropriate, it MUST be THE six places on the assessor's list. One of them is "on a railway track". So, rather than training people to identify hazards, and not park the fork lift in a hazardous place or way, "competent people" know the rule to not park the fork lift on a railway track. No doubt accident / incident driven training... a negative driver. (I will leave you to think about 5 other stupid places to park a fork lift!)

There is usually sufficient reliable input to recalibrate. However, it does leave open the possibility that we can be fooled or exploited by something resembling what we think we know.

5553. Would a discone cover all the US TV broadcast Freqs?

Newsgroup: rec.radio.amateur.antenna

I want to put up the smallest outdoor antenna that would cover all TV Broadcast Freqs being used after Feb 2009. The log-periodicals are too "un-stealthy" to go unnoticed by the XYL, but I think a little discone with some black paint might escape her inspection as long as I do the installation while she's out shopping.
Question is - have any of you used one for TV - and if so, how did it perform? would it cover the TV broadcast freqs ? (I'm aware of its lack of gain - I'm within 5 miles of most local stations, and within 20 miles of a couple more.)
Thanks
Hal W4PMJ

It should work just fine, barring multipath. Multipath with digital signals does not produce ghosting, just signal degradation, although it can be so bad as to make viewing spotty with dropouts. I'd give it a go if I already had the antenna.

Discone is vertically polarized and TV is horizontal. Results in a 15db or
more loss in signal.

Hello contributors to my Excel problem,

Though I am not an SW guy, I solved my Fresnel diffraction problem
with Turbo Pascal 5.5. After playing with some basic Pascal things,
it took limited time to write the routines. The speed of the
calculations surprised me. I think they did a really good job at that
time.

For the time being, I use MS excel for the graphing part.

Thanks for the help!

Best regards,

Wim
PA3DJS

www.tetech.nl
When leaving out abc, you have a valid PM.

At five miles an old coat hanger would probably work well. Years ago I
lived in a townhouse apartment that had cable but you bought it
through the apartment at a premium rate compared to the cable company.
I put a coat hangar dipole in the attic and connected it to there
wiring. I got ABC, CBS,NBC 3 PBS stations and a couple of local non
affiliated stations. Way more TV than I wanted.

It probably won't take too much antenna of anykind to get the digital
signals. I bought a converter for an old set and hooked it to a 432 antenna
about 20 feet off the ground and got about 20 stations. Then hooked it to
a M2 9 element 2 meter horizontal beam at 60 feet and got 29 stations on
autotune. I am probably 20 miles or more from the nearest station . More
like 30 or 40 miles from most.

AKA a Bi-Conical..

That's basically what a George Brown Super Turnstile uses.. Fan dipoles
which approximate a biconical.

Seems like a waste of a perfectly good pair of communications discones,
to me. If the original poster is looking for a low visual antenna in place
of the sometimes large TV Yagi's, he might take a look at antennas made
for the RV industry.

Personally, I'd homebrew something out of brass welding rods.....
perhaps a few stacked horizontal loops......

If I did that, the omi-directionality (if that's a word) would go away and
so would most of the compactness needed foe stealthiness.
So - does anyone know of an omni directional horizontally polarized wide
band antenna?

I like making my own also - so would a few 'nested loop' antennas cover the
tv broadcast band? But there goes the stealth.

Huh? You think a couple brass welding rods in loops are more
noticable than a couple discone antennas mounted base to base? ! And if
you painted them black, they'd be invisible.

Had something like that on the roof of my RV. A Wineguard Roadstar
2000 omnidirectional antenna ought to be just what you're looking for.
Paint it black, if you want even more stealth.

If you want a truly-omnidirectional (or close to it) antenna, with no significant pattern variation or serious sensitivity variation in frequency over the TV band, horizontally polarized, with no requirement for electronic switching of elements and no mechanical rotator... I sure don't. I skimmed through the antenna designs given in Bailey's "Television and other Receiving Antennas" book a few days ago, and didn't see any which come close to this.

I think you're going to have to "give" on at least one of the above issues in order to get something realizable.

There are probably a number of approaches:

- Use a wideband, rotatable dipole. At least one of the "saucer radome" antennas comes with an internal rotator, control box, and IR remote. You program in the bearing to each station you want, hit a button on the remote, and the rotator swings the (inside-the-radome) elements into line. See the HDMS9100 antenna at the top of the page:

http://www.starkelectronic.com/allomni.htm

In this approach you give up on "no rotator". Doesn't work terribly well with DVRs, since the DVR may have a scheduled recording to make and can't push the button to rotate the antenna.

- Use a wideband dipole (e.g. several dipoles of different lengths, mounted in the same plane, with a common feedpoint), and simply align it in a way which gives you acceptable signal quality for all of the stations you care about. The null off the end of a dipole isn't all that wide, and you may find that you may be able to "aim" these two nulls in a direction which doesn't place any of the transmitters into a substantial null. There may be one or more "compromise" settings in which you get a plenty-good signal on all of the stations.

In this approach you give up on true omnidirectionality.

I think that the Channel Master 3000A (listed further down on the page above) is of this general sort. If I recall correctly, it has a single folded dipole element internally, with the ends of the dipole swept into an "S" shape in side the radome - this lessens the depth of the null off the end and (I think) makes the direction of the actual null somewhat frequency-sensitive.

- Install two such broadband dipoles at 90-degree angles, with a remotely operated switch/relay, and select one or the other depending on channel.

Not truly omnidirectional , requires manual switching.

- Install two or more dipoles of different lengths, at different angles, with a common feedpoint, with each dipole cut to the frequency of a specific station and aligned broadside to that station's transmitter. The resulting pattern will no doubt have lobes and cancellations, but (if the channels are far apart enough in frequency) will probably work reasonably well.

Not truly omnidirectional at any single frequency; needs to be designed for your specific location and frequency considerations.

Huh back to you - I never said anything about a 'couple' of discones - my original post was asking whether a discone would be a viable tv antenna. and I mentioned that I wanted to preserve some degree of stealth as well. Your suggestion sounds good - just trying to picture it.
That RV antenna is starting to sound good too.

Usually true. However, a few DTV stations have a vertical component
intended to improve mobile TV reception, where a telescoping vertical
whip antenna is commonly used. See:

A closer reading (skimming) would reveal:
Data sheet 10-15 Biconical Full Wave Antenna
Data sheet 10-30 Crossed Dipoles (Turnstile)
Data sheet 10-32 Slot Antenna
Data sheet 10-33 Slotted Cylinder Antenna

Basically, the take-home for widebandedness is a thick antenna (or its skeletal equivalent). Many are vertical designs, but you simply build the mirrored half and turn the assembly 90 degrees.

Although not the widest of designs (but wider than most), I would add the Inverted F, example to be found at:
http://www.qsl.net/kb7qhc/antenna/Inverted%20F/index.htm
Make it thicker to make it wider (or fan out the segments). This is a very low profile antenna by the way.

As for Ed's repeated advice for paint it black (Rolling Stones?), no. Paint it off-white or a paler shade of blue (Procol Harumish). In experiments during WWII, they discovered that lighting targets against the sky made them disappear - not darkening them which offered contrast. Oxidized aluminum is probably the best coloration.

ATSC ignores much multipath.

Somewhat tricky..

Two crossed dipoles fed with the correct phasing is very close to that.

Check out "Lindenblad" or "turnstile"

A "big wheel" is omni and horizontal, but not especially broadband.

No, not Rolling Stones.... never was a fan. And I stand corrected. I know better, but here in Oregon, most of my outside stuff has a "dark Green" folage background and I was thinking of that instead of the sky.

Well, heck yes!

I see dead people (ghosts) on my TV screen all the time, don't you? If not, get some old reruns of Gunsmoke on, you'll see 'em! :-|

The tricky part, I believe, is maintaining the correct phasing between
dipoles over a sufficiently wide frequency range.

For narrow-band applications, using an additional quarter-wavelength
feedline phasing section would do.

For somewhat wider-band applications (say, 2:1 frequency range) a
broadband 90-degree hybrid ought to work... Minicircuits sells some
such.

I'm not at all sure how to do this for an antenna intended to cover
everything from VHF low-band up to the 700 MHz end of the new UHF
channel range. This is more than a full decade of frequencies... is
there a single broadband 90-degree hybrid that can do the job?

It feels like it might be necessary to split the signals into multiple
bands (VHF / UHF at least, possibly VHF-low / VHF-high / UHF) and then
do the phase shifting on each band individually and then recombine.
Pretty complex...

Or is there an approach I've missed?

A Lindenblad array (e.g. http://www.bbc.co.uk/rd/pubs/reports/1991-15.pdf
Page 9) can provide good circular polarisation over much of a sphere and is
a relatively complicated antenna to design if it is to match properly -
probably over the top for the stated application. But the turnstile, and
the Alford loop
(http://books.google.co.uk/books?id=1KLTUWLz8jcC&pg=PA123&lpg=PA123&dq=alford+loop&source=
web&ots=6hiP0dgh2_&sig=uiCwYvutcxk6lW9AnpXZDHI2ZpA&hl=en&sa=X&oi=book_result&resnum=2&ct=r
esult#PPA123,M1
as used at DVOR stations), are simpler and can provide good omni patterns in
the horizontal plane and thereabouts for horizontal polarisation.

Chris

Why not just put a normal antenna up in the garage or the attic? A small
yagi should do it. You can remove the UHF reflectors if there is plenty of
signal. Even cut half of the UHF directors without much loss. Bring it up
in the rafters and spread it out. Not near as good as on the roof but you
can always put it up normally when she finds out about it anyway.

That last sentence is the point here. She'll find out anyhow.

Hal, it might be time for the "talk". My XYL hates antennas. When I wanted to put up my dipole and vertical, she groused a lot about it. My reply was that I keep the yard beautiful, put in lots of landscaping, and a pond. Now I would like to have a couple antennas for my hobby that are pretty unobtrusive. Maybe I'm in the wrong hobby? Maybe I should take up going out to bars, and hanging out with loose women. At least with radio, you know where I am every night.

The antennas went up.

Got the last one!

However, every once-in-awhile, one is "traded in" (low milage, only one owner, good paint, etc.) and becomes available ... I'll keep my eyes open for ya'.

However, I got a "model/make" from Texas. Couldn't find a decent "model" made in California! (complete! with authentic Texas accent. :-))

5596. Vertical Monopole Radiation Characteristics

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-20 00:02:08 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <16a67e23-cc66-4620-8c7d-63b167b86b66@a26g2000prf.googlegroups.com>

Below is a recent post to another server, which also should be of interest here.

The "SOMEBODY" identified below is well known in the amateur radio community.

RF

++++

“SOMEBODY” wrote: \\ As long as we are screwing up a perfectly good thread about VHF antennas with nonsense about BC antennas, let's try to understand why a 5/8th wave has fading on the fringe.

The reason is the ground losses are so high the skywave lobe is dominant. The skywave is dominant even though the skywave path is significantly longer and the ionosphere has a great deal of attenuation. //

Not wanting to hijack this thread, but also not wanting to let stand the incorrect information posted here by “SOMEBODY”...

Probably most people will acknowledge that the _received_ daytime skywave of a MW AM broadcast station is insignificant in the coverage area of the groundwave of that station, regardless of the frequency and propagation path losses for that groundwave.

The distance to a given AM BCB groundwave field intensity over a given terrestrial path is very nearly the same, day and night. In the daytime that groundwave signal can be received usefully for more than 100 miles from the tx site, for some stations.

At night, the outermost part of the groundwave coverage area also receives a skywave signal from that radiator, which can cause interference to the groundwave (fading) if the two signals have comparable magnitudes, and are not co-phased.

The figure at the URL below was taken from Terman's Radio Engineers Handbook, 1st edition.

http://i62.photobucket.com/albums/h85/rfry-100/TermanFig55.jpg

Note that the single-hop radiation from a monopole that serves distances beyond about 500 miles leaves the monopole at elevation angles of less than about 12 degrees.

Yet a NEC analysis of all monopoles of 5/8-wave AND LESS at an infinite distance over real ground shows very little radiation in this elevation sector. This causes a lot of misunderstanding to those who believe that this NEC pattern is the pattern actually launched by that monopole over real ground.

But it _definitely_ is not. If such monopoles actually launched radiation patterns such as shown by NEC for an infinite distance over real earth, then daytime AM BCB service would be impossible.

There is a nighttime zone where the skywave and groundwave from a given radiator have nearly equal values. The distance to, and the width of that zone are dependent on:

1) Frequency
2) Earth conductivity
3) Radiator height in electrical wavelengths
4) Applied r-f power
5) Ionospheric conditions, and possibly,
6) Earth curvature

(“SOMEBODY” wrote) \\ This is because, even at a distance of a kilometer or less, even the best soil and at a frequency in the broadcast band where the soil is less lossy the earth still has significant attenuation to ground wave signals. //

Here are the field intensity values using the FCC's MW propagation curves for a 1 km groundwave path over a real earth of 8 mS/m, for 1 kW of power on 1,000 kHz, radiated by the stated monopoles:

1/4-wave = 295 mV/m
5/8-wave = 415 mV/m

The groundwave field from the 5/8-wave is about 40% greater than from the 1/4-wave. The field of the 5/8-wave is NOT redirected from in and near the horizontal plane to some high elevation angle as stated by “SOMEBODY”.

Note that both of these values are less than 6% below the inverse distance field for these conditions, over a perfect ground plane. Probably not enough of a loss (0.54 dB) to be called very "significant. "

Also note that my example is for rather average conditions, and not for the "best soil and at a frequency in the broadcast band where the soil is less lossy..." as in “SOMEBODY” ’s description above.

RF (ex-WJR, Detroit)

Ralph E Lindberg wrote:

> ...
> You are aware that many of the DTV signal are UHF band? Right?
>

This:
"Are DTV signals broadcast on special frequencies?

No. DTV broadcasts use exactly the same channels as regular analog
television. While many DTV stations are now occupying UHF broadcast
channels, broadcasters are allowed to move back to their original VHF or
UHF TV channel once the transition to DTV is complete.

The only caveat is that TV channels 51 through 69 will be auctioned off
for other uses at the end of the transition to digital TV. Stations who
originally had analog channels in this band will have to move, no matter
what.

One potential problem with re-using low VHF (2-6) TV channels for DTV is
the possibility of interference from other signals during certain times
of the year. "Skip" may bring in distant broadcasts on the same channel
and create interference. Impulse noise is also a problem on low VHF
channels. Whatï¿½s more, the physical size of low VHF and high VHF
antennas is much larger than that of a UHF antenna.

Tests so far seem to indicate that high VHF channels (7-13) are quite
well suited for DTV broadcasts, and many broadcasters plan to move back
to their high VHF channels at the end of the transition. VHF
transmitters also cost much less money to operate than UHF transmitters."

From here:
http://www.avsforum.com/hdtvfaq/HDTV-FAQ.htm#Are%20DTV%20signals%20broadcast%20on%20special%20frequencies?

Because the bad women get you into fights, jail, divorce court and strip you of your wealth so you wind up paying for their parties while they line up new suckers and try to shame you for not making their fantasies more complete.

Remember their kind of bad is much worse than we give them credit for.

Case in point: Last one had the fantasy that a husband should be willing to die for her. Made her heart go pitter-patter. Thought of men as some kind of pet or other species. I told her to go buy a Doberman.

I find it takes a exhaustive baby-sitting type of investigation of at least 2 years before they let their hair down and show you their true mind.

It looks like marriage is a forgone conclusion in California anyway. I
don't know why the fags want it. I guess they don't reproduce so they have
to steal someone else's kids. It's all beginning to look like reruns of
daytime TV.

What the church should do is Holy Matrimony and quit recognizing the state.

Beware the conspiracy. The problem is that so many people don't even
believe their own experience. let alone what they see happening to others.
"Oh, that won't happen to me." Their brains are too full of slogans that
tell them how to feel and what to say, that they can't make rational
conclusions.

The answer: A Christ centered boot camp that turns marriage partners into accountability partners in a team effort rather than a Detante.

I would like to know when the state/feds took over marriage, why and how
they are able to do it with NO justification. Marriage is a God/Church
thing ...

The same fags which demand they be able to marry will demand separation
of church and state powers; So, where is that separation here. Gov't
needs to back off ... only God and the Church has the power to
rightfully marry people--all other marriages are a fraud anyway.

Below is a recent post to another server, which also should
be of
interest here.

The "SOMEBODY" identified below is well known in the amateur
radio
community.

RF

++++

SOMEBODY wrote: \\ As long as we are screwing up a
perfectly good
thread about VHF antennas with nonsense about BC antennas,
let's try
to understand why a 5/8th wave has fading on the fringe.

The reason is the ground losses are so high the skywave lobe
is
dominant. The skywave is dominant even though the skywave
path is
significantly longer and the ionosphere has a great deal of
attenuation. //

Not wanting to hijack this thread, but also not wanting to
let stand
the incorrect information posted here by SOMEBODY...

Probably most people will acknowledge that the _received_
daytime
skywave of a MW AM broadcast station is insignificant in the
coverage
area of the groundwave of that station, regardless of the
frequency
and propagation path losses for that groundwave.

The distance to a given AM BCB groundwave field intensity
over a given
terrestrial path is very nearly the same, day and night. In
the
daytime that groundwave signal can be received usefully for
more than

100 miles from the tx site, for some stations.

At night, the outermost part of the groundwave coverage area also
receives a skywave signal from that radiator, which can cause
interference to the groundwave (fading) if the two signals have
comparable magnitudes, and are not co-phased.

The figure at the URL below was taken from Terman's Radio Engineers
Handbook, 1st edition.

http://i62.photobucket.com/albums/h85/rfry-100/TermanFig55.jpg

Note that the single-hop radiation from a monopole that serves
distances beyond about 500 miles leaves the monopole at elevation
angles of less than about 12 degrees.

Yet a NEC analysis of all monopoles of 5/8-wave AND LESS at an
infinite distance over real ground shows very little radiation in this
elevation sector. This causes a lot of misunderstanding to those who
believe that this NEC pattern is the pattern actually launched by that
monopole over real ground.

But it _definitely_ is not. If such monopoles actually launched
radiation patterns such as shown by NEC for an infinite distance over
real earth, then daytime AM BCB service would be impossible.

There is a nighttime zone where the skywave and groundwave from a
given radiator have nearly equal values. The distance to, and the
width of that zone are dependent on:

1) Frequency
2) Earth conductivity
3) Radiator height in electrical wavelengths
4) Applied r-f power
5) Ionospheric conditions, and possibly,
6) Earth curvature

(�SOMEBODY wrote) \\ This is because, even at a distance of a

kilometer or less, even the best soil and at a frequency in the
broadcast band where the soil is less lossy the earth still has
significant attenuation to ground wave signals. //

Here are the field intensity values using the FCC's MW propagation
curves for a 1 km groundwave path over a real earth of 8 mS/m, for 1
kW of power on 1,000 kHz, radiated by the stated monopoles:

1/4-wave = 295 mV/m
5/8-wave = 415 mV/m

The groundwave field from the 5/8-wave is about 40% greater than from
the 1/4-wave. The field of the 5/8-wave is NOT redirected from in and
near the horizontal plane to some high elevation angle as stated by
�SOMEBODY�.

Note that both of these values are less than 6% below the inverse
distance field for these conditions, over a perfect ground plane.
Probably not enough of a loss (0.54 dB) to be called very
"significant. "

Also note that my example is for rather average conditions, and not
for the "best soil and at a frequency in the broadcast band where the
soil is less lossy..." as in �SOMEBODY� �s description above.

RF (ex-WJR, Detroit)

Hello ex-WJR, I am old enough to remember station breaks
running This is the Good Will Station WJR, Fisher Building,
Detroit.
The idea that coverage is maximum for the 5/8th wave
radiator is common but in practice, (maybe we are saying the
same thing) a straight 1/2 wave may have a smaller fading
ring because it does not have the high-angle lobe wich
appears on the 5/8th wave pattern. I certainly agree that
patterns calculated for "ideal" ground are not matched by
practical ground systems except, perhaps, sea-water grounds.
The fading ring is one reason very high power BC stations
don't work well at night. I don't suppose many AM
broadcasters think nighttime coverage is important these

days but in antidiluvian days it was considered very important. Edmund A. La Port give all this good coverage in his old book which is available on line from Pete Millett's site at:
http://www.pmillett.com/

First off, "separation of church and state" is cited nowhere in The
Constitution, neither does "freedom from religion." In fact, First
Amendment was placed that no particular denomination would be made the
official religion of The State. But not only would a belief in God be
respected, but considered necessary and in fact, God is cited as the primary

justification for the very existence of, and the authority of, The State. When The State kills off God, then it usurps it's own authority.

AFAIK marriage was mostly a registration thing to start with, then it progressed to further regulation and intervention "for the sake of the children" as in rh factor typing, and tax credit, then on to legal authority in breaking up families and assigning child support and custody which has now become a complete Socialist joke since they have been awarding adoption and custody of even same sex children to gays so they can "indoctrinate" which really means "grooming" or preparing for rape by force, intimidation or bamboozle. They may claim they aren't really child moles_rs, but how can you believe that when someone aggressively promotes "lust of the flesh" or "sexual gratification" as an alternative to God's way. If it were only about LOVE there wouldn't be a discussion because in the end we would be brothers and sisters in heaven, not Plaintiff and Defendant, Gay or Straight, so as a people we seem to be "delivered over to a reprobate mind" and our government is only a reflection of that.

The sickest argument put forth is the "Scientific" argument, that it is only natural. But that argument works as well for even cannibalism, since it occurs in nature too. So what separates us from being animals?

The real enemy after all is the Devil. He is International and infiltrates anywhere he finds an empty thought.

Get help, JB. You can say all this stuff in some of the more psychotic churches in this country and maybe get some people to think you're wise and prophetic, but this is a forum for antennas, not the evils of consorting with devil-worshiping Thai ladyboys. On this forum, you're simply making a paranoid old fool of yourself.
Hope you get well, soon,
73,
Tom Donaly, KA6RUH

5617. Re: Vertical Monopole Radiation Characteristics

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-22 12:37:09 UTC

> radiator is common but in practice, (maybe we are saying the
> same thing) a straight 1/2 wave may have a smaller fading
> ring because it does not have the high-angle lobe wich
> appears on the 5/8th wave pattern.

My comments also were addressing the belief of the OP that the peak gain of a 5/8-wave vertical was very little different than for a 1/4-wave, because of a high-angle lobe developed by a 5/8-wave.

It is true that such a high-angle lobe develops to some extent for all vertical monopoles between 1/2-wave and 5/8-wave in electrical height. This can be seen in the plots linked below (FCC method).

http://i62.photobucket.com/albums/h85/rfry-100/MWElPatComparison.jpg

But regardless, the 5/8-wave has the greatest peak gain of the five monopoles shown.

In situations where the combination of frequency, earth conductivity etc (my 6 points above) limits the useful groundwave coverage radius closer to the transmitter site than is served by the high-angle lobe from a 5/8-wave radiator, then the 5/8-wave would produce the greatest fade-free groundwave coverage area day and night (other things equal).

However this isn't the case for most "Class A" (50 kW, non-directional day/night) AM stations. The most common radiator height used by them is about 195 degrees, which provides a little more groundwave range than a 1/2-wave, and about the greatest distance/smallest width for the fade zone. WJR, in fact, uses a 195 degree vertical.

> I certainly agree that patterns calculated for "ideal" ground
> are not matched by practical ground systems except, perhaps,
> sea-water grounds.

The FCC approach for AM broadcast stations is to use the pattern/gain of the radiator over a perfect ground as a basis for the groundwave field intensity at a given distance over real ground, as determined by the FCC's MW propagation curves -- which curves are based on real-world, measured performance.

With the advent of NEC and NEC-2, some have been misled by the elevation pattern shown for a vertical radiator at an infinite distance over real ground as being that of the radiation launched by that vertical radiator. But it is not, it is only the amount of that original radiation that survives at an infinite distance, for those ground conditions (and for flat earth, at that).

This has led to the concept of a "take-off angle" from a ground-mounted vertical where peak radiation occurs, and that little to no radiation occurs from the monopole in and near the horizontal plane. But that isn't the case -- the relative field over real ground at low elevation angles close to the vertical radiator can be very high, and will continue onward to produce a long-range skywave. Even radiation at an elevation angle of one degree will reach the ionosphere, due to earth curvature.

The theoretical elevation patterns shown in my plots don't exist very far from the antenna, but they are a closer to reality over real ground than those shown by NEC and NEC-2 for an infinite distance over the same ground, and assumed also to exist close to the radiator.

The results obtained using NEC-4 to calculate the groundwave field intensity within the useful daytime coverage areas of AM broadcast stations give much better correlation to the measured fields, and to the methodology of using the theoretical pattern with the FCC's MW propagation curves.

NEC in its various forms is an excellent means to evaluate the
radiation from various structures.

But without due care it still can lead to incorrect conclusions about
system performance when propagation effects are present -- as in the
recent thread here about the elevation patterns of MW monopoles.

Here is another situation...

http://i62.photobucket.com/albums/h85/rfry-100/GroundPlaneElevPatCompare.jpg

The example above does not compute the surface wave.
The following card computes "Space Wave plus SurfaceWave":

```
CM 144 MHz Vertical Dipole
CE
GW 1 13 0 0 33.15 0 0 30 0.010417
GS 0 0 0.304800
GE 1 -1 0
GN 2 0 0 0 13.0000 0.0050
FR 0 1 0 0 147.3 0.1
EX 0 1 7 0 65.66981572 0
LD 5 0 0 0 3.801E7
RP 1 11 1 0000 0 90 1.00000 1.00000 50000
EN
```

In this example the vertical half wave dipole, with the base 30 ft above
an average ground, on 147.3 MHz, shows a field strength at ground
level of: 0.418 uV/m from 30 W into the antenna.

Yeah, a look back though history provides all sorts of weird things.
Like, the king decided who could and could not marry, had dibs on having
sex with the bride first, etc. Like I said, gov't has no place in
religious affairs--end-of-story.

>
> The sickest argument put forth is the "Scientific" argument, that it is only

It looks pretty natural to me. Not only that, but it is the only way to have a stable society where there the children are well taken care of. But, your logic evades me; Can a dog behave any other way than as a dog? A cat? A bird? A mouse? Etc ...

>
> The real enemy after all is the Devil. He is International and infiltrates
> anywhere he finds an empty thought.
>

The bible brings us stories of another race(s) which are not benign to the human race. If these stories are true, or not, I do not know. I do know that behind any "myth", there is always a grain of truth ... ancient books from India, written on palm leaves bring us stories to rival Buck Rogers, spacecraft and wars in and out of our atmosphere--I find it strange that ancient people had such a strong affinity for science fiction ... it actually boggles my mind; I wonder ...

However, I do not hold any to my own thoughts, or open-mind. And, we waste a thread which follows the intent of antennas a whole lot more than our meanderings of mind ... I must make this the end of my story. Again, if we would agree, I would be bored ... thanks for not boring me. :-)

Warm regards,
JS

There is much truth there. It seems humans are constructed with a need to worship "something." In the absence of a loving God, we get a stern and vengeful state ... wait and see.

Your statement is one of the most correct I have ever seen offered in
this group.

However, it, NEC, still remains one of the best available "antenna
prediction" offering of software obtainable to "normal" people ... and
provides some sort of an income for those who write the GUIs' who feed
the text file to it ...

Here is another method (Longley-Rice) for calculating the field intensity produced at the receive site by your model. But the NEC approach is less accurate than L-R for long path lengths (due to earth curvature), and for specific terrain contours.

In your model the path loss calculated using L-R is about 68.8 dB more than the free space loss. The peak, free space field produced by a 1/2-wave, linear dipole radiating 30 watts over a 50 km path is about 770 uV/m. This voltage reduction of 68.8 dB is a field multiplier of about 0.00036, so the 770 uV/m field is reduced to about 0.28 uV/m -- a bit less than your NEC model predicts. Agreement probably would be better over shorter paths (as long as no specific terrain profile needed to be applied), and worse for longer paths.

In the L-R example I set the path over the middle of Lake Michigan in order to get a smooth earth contour, such as used in NEC models.

This all just illustrates that analyses made using NEC and any other method need to consider the limits inherent in their algorithms with respect to the physical reality being analyzed.

> the
> same thing) a straight 1/2 wave may have a smaller fading
> ring because it does not have the high-angle lobe wich
> appears on the 5/8th wave pattern.

My comments also were addressing the belief of the OP that
the peak
gain of a 5/8-wave vertical was very little different than
for a 1/4-
wave, because of a high-angle lobe developed by a 5/8-wave.

It is true that such a high-angle lobe develops to some
extent for all
vertical monopoles between 1/2-wave and 5/8-wave in
electrical
height. This can be seen in the plots linked below (FCC
method).

http://i62.photobucket.com/albums/h85/rfry-100/MWElPatComparison.jpg

But regardless, the 5/8-wave has the greatest peak gain of
the five
monopoles shown.

Snipping here..........

I was not disagreeing with what you say above, perhaps
I did not express it well.

Once you get away from the near field, there's tons of models and modeling approaches available, depending on the kind of path you're interested in, and what you're looking to find out. For instance, ioncap and its ilk (VOACAP,etc.) model skywave paths in a statistical sense. Other models do raytracing for a more "point solution" type model. Yet others are good for things like forests or terrain.

Since nobody has a full up computed electromagnetics finite model of everything at fine resolution, all those models basically trade off computational resources against some approximations. Whether it's approximating the earth as flat surface of a uniform dielectric (NEC) or whatever..

RF

Interesting comparison between methods at VHF frequencies. For curiosity
I had done a comparison between the FCC predicted curves, for an AM
broadcast station on 1655 kHz, and NEC. It seems that at the lower
frequencies NEC has greater accuracy. Of course NEC was never intended
as a propagation tool, but still appears to be reasonably useful. I had cut
and pasted an Excel spread sheet below, so not sure if it will retain the
formatting when posted.

Frank

Field Strength Comparison at 1655 kHz..

Antenna Description: 45.3 m ground mounted monopole. 120 X 45.3 m
radials, 15 cm below ground. All conductors copper.

The Government struggles with taking care of all the stupid minions, trained to fail for generations, that desire to be taken care of or need to belong to something at any cost, with an ever present temptation to either wipe them out or let nature somehow wipe them out to ease the burden. The collapse of the economy of the Soviet Union meant that despite the atrocities, it could have been a whole lot worse for a lot more people (perhaps the collapse itself was little more than an abdication of responsibility while hard-line idealists regrouped- I digress.). Perestroika was blamed for the fall, but economic realities resulted in that panic jump into a new course they knew nothing about. Look at how many new business fail because the owner doesn't even have a business plan. Now there is a knee-jerk reaction to old ways that never worked. It could be compared to the South after Reconstruction. Suddenly the slaves were free, but few knew how to prosper.

We still haven't found rock-bottom in the disaster we have incurred with so much Social tampering in our society. Even as of several years ago, I spoke to some people who straight faced hoped for another national crash, fall, and depression in the hopes that another leader like Roosevelt could emerge. An honest analysis of the depression era clearly shows that none of the so called progressive programs actually brought us out of the Great Depression. In fact many of those programs actually prolonged the misery. Recovery was actually credited to Shirley Temple and W.W.II. At least Shirley often gave the glory to God.

The credit for alleviating suffering throughout the World still goes to God. Even FEMA credits Christian charity and volunteers for far more than they ever could have done when referring to Katrina.

BTW anyone who doesn't get any part of this, just ask for a clarification. It can be broken down and s'plained in more personal terms. As for the

discone question, it was well answered and covered long ago.

In fact, if devil-worshipping Thai ladyboys are influencing or making public
policy regarding local zoning laws, it could have a great effect on your
available antenna choices.

Thanks, It's good to find people that acknowledge history.

Dogs have been brainwashed and bred for specifics in temperament,
appearance, behavior. Cat's seem to resist that and are bred more for
appearance. Humans are more like dogs it seems, except for the capability
to commune with God, and thus be able to raise itself by providence where
the dog just seeks to address basic needs and desires.

You need to find the movie "Idiocracy" on DVD. That will blow you away as
well as any papyrus leaf science-fiction. Some Crude humor, language and

situations resulting from an experiment in suspended animation that goes awry. A hooker and an Army file clerk are put into suspended animation, then lost in the shuffle until 500 years later, the Great Garbage avalanche accidentally releases them in a future where they are the smartest people on Earth, just in time to save the planet.

Dear Group: What a delight it is to see a computer doing the calculations for VHF propagation.

Almost fifty years ago, I led a team who measured field strengths in the 100 to 250 MHz range (FM and TV broadcast transmitters) to verify (qualify) the propagation model. Of course, I used a slide rule and log tables to perform the calculations and manually extracted path profiles from topo. maps. The goal was to place confidence in the model for estimating expected interference levels at a radio-astronomy site located in a valley. The result from extensive filed measurements and data reduction was that we could be confident in the model.

I recall also doing some comparisons of predicted and measured strengths involving scattering (over quite long distances) in the VHF range with good correlation.

IONCAP, and its predecessors and successors, I have used to good effect for almost as many years.

In short, the developed propagation methods have been proven by me, and many others, to provide reasonably small uncertainties. Of course, the critical element is knowing which tool to use. That, I believe, is part of the point brought forward by Richard Fry and others. But put yet another way, any dam fool can (now) put numbers into a computer and get numbers back out of the computer - experience and judgment is needed to have significance accrue to the results of such calculations.

Central to all of the propagation models is the need to understand what the antenna and its environment actually does. I am also delighted that several of you are providing the education to the silent so that they do not fall into the traps that are always present.

Warm regards and season's greetings, Mac N8TT

Here is another method (Longley-Rice) for calculating the field intensity produced at the receive site by your model. But the NEC approach is less accurate than L-R for long path lengths (due to earth curvature), and for specific terrain contours.

In your model the path loss calculated using L-R is about 68.8 dB more than the free space loss. The peak, free space field produced by a 1/2-wave, linear dipole radiating 30 watts over a 50 km path is about 770 uV/m. This voltage reduction of 68.8 dB is a field multiplier of about 0.00036, so the 770 uV/m field is reduced to about 0.28 uV/m -- a bit less than your NEC model predicts. Agreement probably would be better over shorter paths (as long as no specific terrain profile needed to be applied), and worse for longer paths.

In the L-R example I set the path over the middle of Lake Michigan in order to get a smooth earth contour, such as used in NEC models.

This all just illustrates that analyses made using NEC and any other method need to consider the limits inherent in their algorithms with respect to the physical reality being analyzed.

Hi Mac, and season's greetings,

Can you relate the specifics of the measurement? At a minimum, what
you would deem to be your best accuracy compared to an absolute
standard, or to a relative standard (instrumentation, not
computational).

Dear Richard:

It was almost 50 years ago when the models were rather new.....

More background: the terrain was hilly - far from smooth earth - and path profiles were a critical part of the information along with the inherent uncertainties of using "analog" maps and along with the assumption about almost-straight line propagation. (an aside: we found examples of unpredictable propagation along string-like valleys that were aligned with transmitters, but the protected site was in a bowl-like valley.) (I saw one family in a valley using a rhombic antenna to receive TV signals. Their son had been in the Signal Corps.)

We were using state-of-the-art Empire measuring systems (run off of a portable gasoline generator) that were calibrated with an impulse generator at each measurement. We selected paths that were similar to the expected paths of interfering transmitters. In other words, the paths were more-or-less normal to ridge lines not along string-like valleys.

One more qualification: one path was found to have knife-edge diffraction discovered by the caution of taking measurements spaced a few meters apart at each data point. It was absolutely classic, but that data was not used because the protected site did not have such sharp ridges at its periphery.

With those qualifications, my best recollection is that measurements and predicted measurements were within something like 3 or 4 dB. I doubt that repeating those measurements with a GPS receiver, digital topographical map, averaging near straight-line paths, and using a computer to do the arithmetic would be any better.

Another note: Because of the expected sensitivity to interference at the site, I would drive over a few hills, erect a dipole in trees, and work my father on HF from the back seat of my car. No cell phones in those days. ... long distance was a big deal too

Let us know how your studies are going. Warm regards, Mac N8TT

You weren't asking me, but still you may be interested in the link below which leads to a good presentation of this by the NIST. A table on Page 3 there shows a measurement uncertainty at the NIST test facilities of ±1/4 to ±1 dB, depending on the DUT and the frequency range.

Field intensity measurements made using uncontrolled path conditions are more a measure of the propagation environment and the pattern/ location of the receive antenna than they are of the absolute performance of the transmitting antenna system. Such measurement errors can be gross, and difficult to quantify.

Dear Richard Fry:
Thank you for the 1985 reference, which I had not seen before. Too many IEEE groups exist!

A closed-loop system much like that shown in Figure 15 was built by me and a student and used by the mid 70s to subject DUTs to up to at least 200 v/m at frequencies up to about 200 MHz. This was for automated evaluation of the EMC of relatively small DUTs and was the prototype of a much larger system implemented by a major manufacturer that allowed the testing of entire cars. This was well before PCs, but after 488 signal sources and wattmeters were available. Confidence to about 1 dB was felt because of the tight correlation with a short voltage probe extending into the TEM cell. Unfortunately, the small effective volume of the TEM cell precluded measurements of antennas. The large room at NBS allowed them to measure antennas and I saw them measuring a large UHF antenna with a near-field probe in the early 1970s.

Jumping to HF antennas of 0.5 WL size or more: I am convinced that even with a helicopter being used to measure a pattern, one can have more confidence in the result of the intelligent use of NEC4 than in any measurements.

The measurements made in late 50s (to gain confidence with VHF propagation models) involved cherry-picking the paths to correspond with the goal of understanding propagation of possible interference into the radio-astronomy site. They also involved averaging a series of measurements taken within a few meters of each other. The measurement sites were all very rural and free of significant reflecting surfaces.

Warm regards, Mac N8TT

Actually, ï¿½1 dB would be the most likely error for instrumentation
error (ï¿½ï¿½ dB could never be achieved); matching error would compound
that; the antenna would add another ï¿½1 dB; path would scramble that
further if not performed in an anechoic chamber or on a calibrated
range.

Mac's test system (from fig. 15 he reports in other correspondence)
would accumulate up to the several dB he reported earlier. It would
exhibit a very good relative accuracy, but absolute accuracy would be
several dB error as he has already offered in prior correspondence.
Path problems would have to be hammered out on their own.

Folks,

I have purchased a Sangean ATS-909 World Receiver. It is equipped with an internal ferrite antenna för MW and LW, and a telescope antenna for SW and FM. It also comes with a portable SW antenna (ANT-60), seven meters long. Is this external antenna generally sufficient for SW reception, or should I get a different antenna? If yes, is there a solution that doesn't cost all that much money? I have a copy of the 2009 World Radio TV Handbook, and they are talking about a Wellbrook ALA-1530+ loop antenna, and let me tell you, that one is well past my budget, because it costs $466... I am looking for something a lot cheaper... :-) If it is recommended to replace the ANT-60, that is.

Hi PJ,

With your location in Sweden, a long wire should pick up a lot of
stations unless you are buried deep in a valley. That long wire can
be as simple as 10 meters of wire with a clip to attach it to the whip
of the Sangean. When I was in Africa last year, that was enough to
fill my cheap SW set with signals from everywhere in Africa up into
Europe. Toss the wire out a window up into a tree. It is at least a
cheap, first attempt to see if you need anything more than that.

At HF and VHF, you should be able to do power measurements to a tenth of a dB, with moderate care. (obviously, you'd have to deal with measuring the mismatch, etc.). A run of the mill power meter should give you 5% accuracy (0.2 dB) without too much trouble. A 8902 measuring receiver can do substantially better. Even at microwave frequencies, better than 0.1 dB uncertainty (2 sigma) are possible with free space measurements (e.g. from an orbiting satellite to a ground station), with all the uncertainties stacked up (atmospheric, radome loss, antenna, electronics, etc.), although this is decidedly non-trivial.

As mentioned, site effects or chamber uncertainties might contribute more.

A typical anechoic chamber might have -20dB worst case reflections from the walls, and -40dB as more typical. A single scattering path will then contribute an uncertainty (worst case) of 1%, or 0.04 dB, although modern measurement technique (using multiple probe positions) can quantify this error and remove it, assuming the UUT and equipment are stable enough over the measurement period.

The TEM cell is nice because it gives you a way to create a calibrated field to characterize your probe.

Should be very careful when connecting the whip to the ATS-909 antenna
with a metal clip - the radio is quite sensitive and should be turned
off while "clipping". For my connection, I just wound a coil of
insulated wire that would slip over the whip - the inductance alone is
enough to bring in signals strongly, and avoids the chance of possible
static and internal damage. About 20 turns is enough to get you
started; wind more if you want a stronger signal.

Nothing astonishes me more than the simple dash-off notes that claim
power measurement is a snap. I can well imagine, Jim, that you don't
do these measurements with traceability to the limits you suggest.

For the other readers:

We will specifically start with the 8902 measuring receiver. A
premier instrument indeed, but it falls fall FAR short of actually
measuring power without a considerable body of necessary
instrumentation (well illustrated by Mac's observation found in that
fig. 15 already cited). Most claimants peer at one line in a spec
sheet and figure that is the end of the discussion. Glances elsewhere
begins to build the actual accuracy obtainable through the chain of
errors that accumulate. For instance with a 1mW input in the VHF
band:

Internal power standard: ï¿½1.2% and we have yet to look at the
measurement head's error contribution. The so-called "run of the mill
power meters" are drawing close, too close to this precision set's
expensive quality such that their estimation of 5% is already suspect
quality.

Scale error demands a full-scale indication to simple keep the error
contribution down to 0.1% (a 1/10th scale indication would jump that
error to 1%) ï¿½1 digit.

Input SWR with the HP 11792 is rated at 1.15 at worst (I've measured
with far better matches) to that same source's 1.05 SWR adds 0.4%
error. If you are not measuring power at the specific frequency of
the internal source, add more error averaging onwards to 2%.

Things build up from here for just one instrument and its RF head to a
worst case valuation of 5% to 6% error. This further trashes the
observation of "run of the mill power meters" vaunted 5% accuracies.

Of course, in this computation of error neophytes are tempted to
employ the RMS estimation. This clearly reveals those untested in the
arts where bench techs who do their best understand that the RSS

estimation is what pays their salary. Taking a step above skilled bench work to that of a Calibration lab, you buy all the error at face value (hence the term "worst case" that is used by the professionals employed in this art).

THEN we turn our attention to the rest of the bench that holds the remaining components that support the measurement of a power level and accuracy begins to slide drastically. I've been there, and I've been trained to reduce the variables - not an easy task and one that the march of time has NOT improved. Mismatch error climbs like the Himalayas if you don't employ line conditioners (which bring their own mismatch) and isolators (which bring their own mismatch) and so on down the proverbial line towards the source being measured (that antenna every one knows has X amount of power coming from it).

For those who are stunned by this bajillion dollar solution giving them 14% best accuracy (and RSS at that) results, confer with: http://www.home.agilent.com/upload/cmc_upload/All/EPSG085840.pdf and observe the commentary for slide 36.

See if you can cook up a method that doesn't hammer you into the ground. I can anticipate some:

1. Throw a box car of money at the problem;

2. Buy lab time at NIST;

3. Write a report that runs to book length (I've carried most of that water by providing the link above) - or xerox the book that already exists: "Microwave Theory and Applications," Stephen F. Adam;

4. Do it with precision components employing best practices to the best achievable accuracy - you will need further instruction into best practices, however;

5. Ignore reality.

Only the last two options are achievable by the ordinary Ham. To claim that "someone else" can do it better and is thus achievable is sophistry serving ego in an argument.

PJ,

I've discovered there is no best antenna for everyone for shortwave listening. Ignore the trolls here, start off with your wire antenna, then experiment if you wish. I've tried a few things over the past few weeks and for me, just running a wire along the ground about 60 feet works best for me. I guess the only certain thing is that an antenna that runs outside will work better than an inside antenna. If you can't run one outside, try to put it by a window or up high in your house/apartment. Experimenting is part of the fun, just google around, play around, and have hours of fun on your new radio. I only in the last few weeks have rediscovered listening to SW radio.

Happy listening.

5652. HF Vertical in a septic leach field

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-24 04:29:47 UTC
From: Steve Stone <spfleck@citlink.net>
Message-ID: <gisds6dhn1@news.motzarella.org>
Source record: 18826

I have a 5 band Hustler vertical.

Available install space in my backyard is an area adjacent to my septic system leach field.

I really don't want to place the antenna in the middle of the leach field and risk hitting an outflow pipe.
If I put it just outside of the reach of the outflow pipes the ground is still relatively moist due to natural run off and the leach field.

So will this leach field moisture enhance or inhibit the verticals performance due to soil conductivity.. or none of the above if the antenna is installed as indicated in the Hustler installation manual. (2 radials per band using insulated copper wire, 4 foot
metal mast pounded directly into the ground, no concrete, no wood).

There is also a 4 foot high chain link fence surrounding my backyard, 300' x 150', one side about 25 feet from the potential install location. No trees or shrubs closer than 15 feet from the vertical mast.

>
> PJ

PJ,

So your objective is to 'buy' a relatively low cost
Antenna for Shortwave Radio Listening (SWL)
to use with your Sangean ATS-909 World Receiver.

Check-Out the / Sangean ATS-909 Users Group
-aka- RadioShack DX-398 Users Group
http://groups.yahoo.com/group/DX398/

Consider using a "Portable Wire Antenna" with your
Sangean ATS-909 AM/FM Shortwave Radio :
http://www.geocities.com/n2uhc/portablewire.html
* WebPage presented by Tom Sevart, N2UHC
http://groups.google.com/group/rec.radio.shortwave/msg/09c73c4c94625fc7
http://groups.google.com/group/rec.radio.shortwave/msg/a789c8fd6fcb38f2

First "About" the Antenna Input of the Sangean
ATS-909 AM/FM Shortwave Radio :
The Sangean ATS-909 uses a 1/8" Stereo Jack
for the External Antenna Input.
Barrel = Circuit-Board-Ground (RF Signal Ground)
Tip = Shortwave Antenna RF Signal Input
Middle-Ring = AM/MW Antenna RF Signal Input

READY-MADE - Shortwave Listener (SWL) Antenna
that fits into the 45 Foot Long Range is the Par
Electronics EF-SWL Antenna. [~$75US]
It come with the Matching Transformer and 45 Feet

of Flex-Weave Wire Antenna Element; and all you
need to do is Install your Ground Rod; Rig the Wire
Antenna Element; and Attach your Coax Cable.
http://www.parelectronics.com/swl_end.htm
http://www.grove-ent.com/ANT8.html
http://www.universal-radio.com/catalog/sw_ant/2205.html

The Par EF-SWL is a moderate size Inverted "L"
Antenna with 'low noise' characteristics : The PAR
is the simplest Antenna for most of these 'portable'
AM/FM Shortwave Radios and lends itself to the
Inverted "L" Antenna configuration of about 45 Feet
long with a 15 Foot Vertical-Up-Leg and a 30 Foot
Horizontal-Out-Arm. With an Eight Ground Rod
at the base and a Coax Cable feed-in-line.

NOTE - Your biggest problem with using a Coax
Cable with your Shortwave Antenna is coming up
with an "Adapter" or Jumper Cable from the Coax
Connector to the Radio's 1/8" Stereo Jack.

Here is another 'low cost' SWL Antenna listed on eBay
"Super Longwire All Band SW. Antenna and 9:1 Balun"
http://cgi.ebay.com/_W0QQitemZ180315835723
* Has 80 Feet of Antenna Wire with a 9:1 Matching
Transformer; plus 50 Feet of Coax Cable.
* Rig as much of the 80 Feet of Antenna Wire in the
Inverted "L" Configuration
* Add an 8-foot Ground Rod
* Run the Coax Cable to you Radio

hope this helps - iane ~ RHF
.

You would have to test the conductivity. If you have good soil conductivity several wavelengths out from your property it will surely add to performance.

The problem with moisture close to the surface is corrosion. Get the ground and coax connections up out of the marsh by a foot and seal them.

It probably wouldn't hurt to carefully dig a post hole so you can feel around, then just fill with gravel.

A pole in the ground does little for RF performance. You can't get resistance low enough to avoid great losses. Currents are greater in the first 1/8 wavelength so there is no substitute for keeping low resistance metal there. Add at least 8 or more full 1/4 wave for the lowest frequency (and preferably 100 more). It will be more critical at the lower frequencies. The 2 per band act as a counterpoise and will help keep RF out of the shack, but do little for performance by themselves. The goal is to capacitively couple to the surface of the ground with a field of multiple radials.

I hate chain link fences. Not a big problem when new, but as they age they actually generate harmonics when you transmit near them. I have a Butternut HF9v on a metal roof. I had to pay attention to hardware on the roof and bonding to the metal carport. Traced bad TVI to corrosion on a nearby TV mast. On a normal roof I would seriously consider running many radials inside the attic, then lightly camo paint the antenna with Krylon Flat Acrylic to match the view from the neighbors and break up reflectivity. Beware though darker colors may detune because of the pigment.

ALA-1530+ loop antenna, and let me tell you, that one is well past my budget, because it costs $466... I am looking for something a lot cheaper... :-) If it is recommended to replace the ANT-60, that is.

This is my favorite:
http://www.antenna.it/military/log-periodic.htm

But seriously folks, the cheapest for me was busting open a junk TV for the deflection coils. A qrp type ham antenna tuner will certainly help. Easy to build L type by using an AM tuning cap and hind wound coil on toilet paper roll. Use a piece of scrap brass for a slider. Put the whole thing on a block of wood and use clip leads to change it around for the best signal.

The earphone jack can often be used for a ground point.

5657. FS Dentron Junior Antenna Tuner

For sale a Very nice Dentron Junior Monitor antenna tuner, tunes a balanced or unbalanced line will handle 300 watts 160 thru 10 meters. Has jacks on the back for coax, ladder line, or random wire. Tuner is in great shape and works fine, tunes all bands with no problems. Includes the original owner's manual. Price is $75. Pictures available. Thanks, Charlie Hugg, K5MBX

Huh, you triggered some memories. Best antenna I ever had was when I
was very young, probably ~8-10 years old, or so. Long-wire which ran
diagonally to property lines of my parents. And, certainly, longer than
120 ft. That antenna filled the bands, as I remember!

No baluns, no matching, no knowledge of what I consider now, krist, it
was most likely a very poor match to the input on the Collins,
Hallicrafters, Zeniths, Gonsets, etc. which it was hooked to. But, ya'
know what? Those were the best times of my life. And, to be absolutely
truthful with you, I did hope to hear aliens--as well as military,
gov't, etc. Some, I accomplished--but, no aliens which I am aware of
... :-(

But, I never have had that much fun in my whole life, since those times
... the rest of life has been rather easy.

I only hope youngsters can still find the same ... :-)

Regards,
JS

When I was in my teensI had access to a 5 mile beverage antenna in the
form of abandoned telegraph lines. I used to plug in the AM radio in

my car to it and listen for AM BCB dx. I could terminate either end and hook up to the opposite end. In the day it was also a great way to park with my date. Yes those were great times.

Me, I avoid paint with pigment. I'm a beefment paint man, myself. <G>

My advice is to just put the damned thing up somewhere and get on the air. Any contact is better than no contact and any piece of metal will provide you with a QSO or two.

Worrying about perfection with an HF9V is rather pointless anyway. Even my old HF6V worked the world when the bands were open. When the bands are closed, nothing works.

Folks,

This is the OP speaking. Thanks for all the various tips and tricks! I don't care much for the unpleasant tone between some posters in the rec.radio.shortwave group, but there are still a few glimpses of good information that I can use.

I was a very keen DX:er in the seventies, and I used a Swedish vacuum tube radio from 1952, named Nornan LV 1220, with a continous SW band from 15 meters to 120 meters. I still have it, and it still works, but I thought that I'd go a little more modern with the ATS-909... :-) Although I think that the LV 1220 is just as good when it comes to SW reception.

I remember that my dream, in the seventies, was to hear the AFAN (American Forces Antarctic Network) SW transmissions here in Sweden. They then used a 1 kW transmitter, and I had heard that someone in the south of Sweden had been able to hear them at some point. Alas, I never did. I am pretty sure that I picked up the carrier wave, but I couldn't hear anything... Bummer... In the 2009 WRTH the AFAN are only listed as an FM station, so I guess that those days are over...

> My advice is to just put the damned thing up somewhere and get on the air.

It has been up for about a month Ed.
I wanted to see what people suggested, since this is the first vertical
I've worked with at my QTH.

Real life results with a IC-746pro and 100 watts on 80m, 40m, and 20m
show this Hustler 5 band vertical as installed works fairly well when
contacts are at least 300 miles or further from my QTH.
Not a flame thrower, but does the job, even from my New York QTH to NWS
offices in Spokane WA and Sacramento, CA.
during SWD.

Only issue is 15m SWR is 3:1 across the entire band, which according to
directions suggest some interaction with objects in my back yard. The
IC746Pro internal tuner can barely tune 15m down to a respectable SWR. I
can tune in 15M if I switch over to a TS-430S and AT-250 external tuner
combo.

For stuff closer in I switch to a 150 foot random wire about 20 feet high.
Come spring I might rework this antenna to be a multi band dipole and
restring it from higher tree branches as long as I can maintain
clearance from the vertical.

My RACES group has the same vertical antenna mounted on the roof top of
the local EOC without radials, about 40 feet above local terrain,
attached to a TS-2000 with about 280 feet of LMR400. I believe the
mounting point is tied into building iron work. We've gotten good
results with SSB on 80 to the state EOC 120 miles away as well as
Winlink Pactor connections to places as far out as British Columbia in
western Canada. We had an option to put it on a 190 foot county comm
tower but I decided not to so we could maintain the antenna ourselves
and not have to wait for profe$$ional tower climbers to schedule repair
actions as needed.

>
> Ed, N2ECW
>
This HF9V works great on all bands but 2 meter (or is it 6). It was a bit tricky to tune even with an analyzer. Low angle incidence on 80 though. Makes it rough for in-state and local comms. Works a lot better on 40-10 than the 4BTV I used.

The 5BTV 10 meter SWR problem may be due to low impedance at the feedpoint. This is typical if the ground is really good. The fence would be too far away at 25' to make a difference in match, although it might shield some energy. Be aware that 4BTV was made in the 60's and radios then had Pi-net plate tuning and there wouldn't be a problem at all with up to 5:1 SWR

An external tuner really helps on 80 because of the Q. Internal tuners on radios really fall short. A really decent internal tuner would take up half the cabinet, so the radio wouldn't sell. Remote auto tuners are really superior. Cuts down on coax losses. Look out for operation outside of the design frequencies or traps will burn.

Merry Christmas all!

Same age-- I ran the wire into a transistor radio and would tweak the
trimmers to go above the broadcast band. Finally got a five band radio,
then upgraded to a Hallicrafters S-110. Most of my vast entertainment
center (set of shelves along my longest wall) was rescued/repaired/cobbled
from junk, and open cabinets and exposed lethal voltages were part of the
mistique. My finger was the best signal generator/voltmeter I owned. By
High School I had my Advanced and 2nd phone and was into Remote Bases, HF,
RTTY and especially liked working on stuff with multiple squelch tails.

Then came computers. I guess I never really outgrew that stuff after all.

My neighbor used to have a chain link fence that generated electrical
noise when the wind blew. I didnt realize what was making all the pops
until the house sold and the new owner put up a wooden fence.

PJ you can't get Antartica anymore as Ace says, but there are lots
more challenging AFN stations to seek out and have fun with. Sadly the
WRTH does not list them conveniently but you can see the full
shortwave spread at:
http://myafn.dodmedia.osd.mil/ShortWave.aspx

You have had lots of blah blah on antenna's, but for your 909 I
wouldn't use anything other than the ANT-60 you have, otherwise you
will overload it and possibly blow the front end.

If you like AM BCB MW DX you might find one of the cheap tuneable
loops provided by the big dealers such as Martin Lynch or Universal of
some help.

Have fun and good listening

I can add a little information that might be helpful.

When considering a receiving antenna, the single thing you need to be concerned about is signal to noise ratio. Unless your antenna is exceptionally poor and/or your receiver exceptionally noisy, making what you receive louder is just a matter of turning up the volume, or adding an audio amplifier if it's not loud enough. But it won't help you hear a station, because it and the noise will get louder in the same proportion.

Quite a bit of what you'll read about antennas deals with improving antenna efficiency. That's because it's important when the antenna is used for transmitting. But when you use it for HF receiving, efficiency doesn't matter unless it gets to be bad enough that your receiver's noise becomes greater than the atmospheric noise it's receiving. A quick test for this condition is to disconnect the antenna. If the noise decreases, it means that atmospheric noise is greater than receiver noise -- the usual case -- and efficiency improvements won't help any. They'll just increase both the signal and noise by the same amount, which won't help you a bit in hearing any signals.

To improve reception, you have to improve the signal to noise ratio. If there's noise coming from a local source, for example a light dimmer or an arcing power line, you can often reduce the noise by using a horizontal antenna, putting the antenna away from the house and power line conductors, and making sure the feedline is decoupled so it isn't part of the antenna. If noise is mostly coming from a single direction, either local or distant, an antenna with a sharp null such as a small rotatable loop often helps. And, other rotatable antennas with a directional pattern such as Yagis and log periodics, will help if the signal and at least some of the noise are coming from different directions. If a fixed antenna is on the order of a half wave or longer, you might get lucky and have a null pointed at a noise source. The null will usually change direction with frequency, though, so it'll likely only do the trick over a narrow range of frequencies. This can actually be a bad thing, because when somebody gets lucky like this, he'll often tout the antenna as being nearly miraculous in its performance, but no one else will be able to duplicate the results.

Enjoy your shortwave listening. It's how I and probably most amateurs got started in this fascinating hobby.

Roy Lewallen, W7EL

I differ; although, I can understand why Roy would reply in such a simplistic manner ...

If the antenna is resonate, matched to its' load, and is not using lossy construction practices--a very magical thing occurs. And, in such a situation, it appears as if a wire runs directly from the transmitter to your antenna. Nicola Tesla first documents this, then others ...

However, most give up before they obtain the knowledge and construction practices which produce such antennas--and, indeed, if you wish broadband antennas, no matter how you construct them, they will only produce this performance on a narrow band of frequencies, or perhaps, just a single one ... but, they can be constructed to preform, reasonably well, over a broadband of frequencies or even bands.

If you have immense focus, devotion to the construction of antennas, a reasonably astute mind, and the necessary skills, a willingness to construct until you have that "revelation"--the realization of all this awaits you. :-)

Warm regards,
JS

Google "traveling wave" or "Beverage antenna" and read up. They can be
built cheaply from wire and are very effective if you have room for
one. If you have an interest in receiving stations from a particular
direction then lay the antenna out in that direction. A terminated
traveling wave antenna is directional and if it's unterminated then
it's bidirectional.

Good luck with your project.

JS - You are replying like and Amateur Radio Operator
[HAM] and are most likely You Are Technically Correct
-wrt- Every item that you have pointed out is very valid
for Amateur Radio [HAM] Operators.

RL - In this instance Knows His Reader and is replying
as a Shortwave Radio Listener (SWL) to the Original

Question : Which was posted by a SWL for Tips on
what would be {how to make} a better SWL 'type' of
Antenna.
-wrt- The SWLer "RL" is Practically Correct.

JS - You speak of Antenna 'resonance' while the SWL
Antenna is by-design a board-banded "Random" Wire
Antenna : Which is often used un-tuned across the
Shortwave Radio Bands from 3~30 Mhz.
Result : On-average-better-Signal-Levels
-and- On-average-lower-Noise-Levels

RL - Is very correct that for the Shortwave Radio Listener
(SWL) : Their Antenna's should give them improved 'better'
Signal-to-Noise : So That They Can Hear More [.]

Oh, yeah!

This past summer I had occasion to haul some bundled antenna sections on the roof rack of my van. I was astonished at the BCB intermod that was generated with every vibration. I think the principal frequency intermoding was a broadcast station about two miles from the start of my trip, since the intermod got less and less as I got further away.

I'm familiar with intermods near transmit antennas, having dealt with EMI on USN ships for many years, but two miles?!?!?

Again, in the narrow context which you describe this, you are correct. But, there is no reason to NOT have an antenna of resonate length. A simple motor and a spring loaded real to take up slack will allow you to construct an antenna of variable length and multi-band capability. Indeed, only ones knowledge, "macguiverisms", and patience limits one ... as opposed to purchasing a product which is solely, usually, based on construction costs alone.

I think the post, of mine, which you are responding to, with your above response, implied all this--I honestly meant to imply such ... or, in other words, you can only get out what you put in with your efforts, time, materials, knowledge, techniques, etc.; Or, i.e., the more thought, design and good construction practices used, the better the

results.

While some of us may search for the most simple constructions, others will go towards the most elaborate constructions--if anyone is like myself, complexity grew with understanding, knowledge, patience, etc.

And, as I implied, Roy gave an answer which would have sufficed for, perhaps, the majority of SWL-ers... I did not fault it (his response), rather I expanded upon it ... no harm meant here, nor did I intend to "slight" anyone! HONEST!

>
> mary xmas

Update
I have made the dish using 1 inch poultry fencing.
The outline of the dish encloses the backfire antenna i.e. the
antenna finishes at the same datum line
as the periphery of the dish. The reason for this is that I am trying
to obtain a zero plus take off angle or
something less than normal with respect to frequency and height using
a planar design
Placed dish on ground with beam pointing upwards and did a swr graph
from 2 to 20 mhz
Repeated above except dish placed at right angles to earth.
Swr for 14 meg hz rose from 2:1 to 3: 1 but both arrangements followed
the same oscillation of SWR.
Difference probably due to variation in dish efficiency.i.e the first
set up was augmented by the ground surface.,
Haven't added the band frequency selection points as yet.
With the graphed impedance curves being similar I am anticipating a
TOA of around
5 degrees when antenna is raised to around 30 feet
Antenna polarisation is horizontal, verticle and cw cwith respect to
gain polarization all being equal in gain, with total gain
being close to 2.5 db in excess of the other polarizations.
As I stated ,the idea is to lower the TOA from that of a normal planar
design.

Comments welcome as well as thrown rocks and sarcasm. I have modeled this type of antenna pointing straight up
but not in a horizontal plane which is why I was able to sugest gain comparables.
Regards
Art

JS,

Alas i am but a simple shortwave LISTENER

I simply LISTEN and 'enjoy' what I LISTEN too

Beyond that; when i LISTEN everything else
is so much technical 'noise'

JS - Enjoy "The Craft" of BEING an Amateur "Ham"
Radio Operator -and- I am sure that you are a lot
more . . . and rightly well deserved too.

js - but alas i remain a simple shortwave listener
who simply enjoys listening to the radio; cause
practically speaking; that is what i do
- - - respectfully ~ RHF
.

SC,
Did you inductively couple the antenna to your whip? If you didn't you
will notice a marked improvement if you do it that way. Just in case
you don't know (I think I posted this already) grab you some wire (I
use 11 or 12 gauge) and tightly wrap five-seven turns around your whip
and cut the rest off. Pull about an inch of the plastic off and clip
onto that. At one time I was doing the "exact" thing you are except I
think my stretch of wire was 70ft. But I picking up a lot rf here and
there, pretty high noise floor on some bands. When I coupled it that
way the noise floor dropped to nothing.

Quit peeing on my leg ...

Brother, I enjoy having a good time, a good drink and the company of a good woman as well as anyone; And, furthermore, I am here because I enjoy a good antenna as well as anyone else.

I am here because some know much more than me, can explain it in a manner which I can absorb (Cecil is but one example), and I expect there is much more for us ALL to learn, indeed ...

I ain't here to lecture you ... I ain't here to be a ham ... I ain't here to play the game of "one-up-man-ship"; I am here to catch what I missed "the-first-time-around"--end-of-story.

But now, a good argument, a good debate, a good "theory-session" ... count me in!

Sit back, and pick on the next guy in line ... ;-)

Regards,
JS

http://www.wellbrook.uk.com/ALA100b.html
With a bit of hacking, the Wellbrook ALA 100 is as good as any of the
shortwave antennas they sell. It is just the amplifier. You have to
roll your own loop. The ALA100 is the lowest cost welbrook. At the
current exchange rate, the ala100 is a over $200.

I have made a few loops with this amp. I have a 2ftx2ft out of copper
pipe for direction finding. I have 4ft x 6ft copper pipe for regular
use. It's really stupid big and will eventually be reduced to the
original 4ftx4ft. I have a few portable designs that are around 40ft
worth of wire.

The wellbrook loops are just amazing. All that said, the ATS909
probably can't handle that much signal. It would make sense to use
one with a portable shortwave radio.

Just like parasitic elements in a Yagi. Yes it does it on RX too. Not only
from the intended signal but chances are there are various closer sources
that can induce voltages in whatever junk is near your RX antenna too.

Very disconcerting to do the lab measurement and getting spurious down 70db
then measure 25db down off the air!?!

A random wire (e.g. inverted L) transmits nicely if you use a tuner at
the feed point.

I don't recognize "politician" as being a monolithic culture. There are decent ones and there are many more shit-heads, but that holds true for society in general.

Actually there is no reason TO have a resonant length antenna if you can tune it electrically. After all, you may want to tune around some. I can tell you it is a pain to have to go out and physically make adjustments for any frequency excursion. There are many nonresonant length antennas that outperform the resonant length. The 5/8 wave vertical comes to mind. A long-wire provides a larger capture area. Then there are phased arrays that reinforce. Look up the HAARP project and see how they made a very large array and were able to electrically steer the pattern. Cool!

The more you know, the cheaper it gets, and the more you giggle when it works. The only problem is you get hooked and want to do so much more.

Actually, tuning it "electrically" *is* tuning the antenna
system to resonance. When I vary my ladder-line length
to achieve system resonance, I am using my feedline as a
series tuning section. When one achieves a Z0-match with a
tuner or by other means, one is tuning the antenna system
to resonance which, in a near-lossless system, results in
near-conjugate match and near-maximum power transfer in
either direction (assuming the receiver input impedance
equals the Z0-match impedance).

Well the idea of 1 inch mesh was a bum idea. I should have kept to my
own thinking.
When transmitters have holes in the casing of 1 inch diameter will be
the time I will use such large holes.
Will now have to take it of and replace with aluminum window mesh.
The present mesh has no idication of working in any sence of the word
Art

- A random wire (e.g. inverted L) transmits nicely
- if you use a tuner at the feed point.

Dave,

IIRC a good Amateur Radio 1/4 WL Vertical-Up-Leg
by 1/4 WL Horizontal-Out-Arm {Inverted "L" Antenna
requires very little Tuning and performs very well near
and far on the HF Band that it is 'cut' to use on.
Using a direct-connect or 1:1 UnUn at the Feed-Point

* Half-Wave Inverted "L" Antenna : 1/4 WL + 1/4 WL
http://www.bloomington.in.us/~wh2t/invertedl.html
http://www.antennex.com/preview/archive3/ltv.htm
* Yes a "Tuner" can help on other bands.

Where-as the more common Shortwave Listener (SWL)
type of {Random Wire} Inverted "L" Antenna is un-equal
and usually has a shorter Vertical-Up-Leg and a longer
Horizontal-Out-Arm of at least 1V-to-2H and often
1V-to-3H or more. Using a 9:1 Matching Transformer
and Ground Rod at the Feed-Point which is at the base
of the Vertical-Up-Leg.
* Again the Wellbrook Drawing
http://www.wellbrook.uk.com/images/antright.gif
http://www.wellbrook.uk.com/longwire.html

as usual it's the 'l' if i know - iane ~ RHF
.

No he's not. He's a bigger horses ass than nearly
anyone on rraa.. :/
And that's a fact. Only "John Smith" might give him
a run for his money in that dept. :/
But I'm not a whiner like Telamon, and try to tell
people what groups to use, or avoid.
They have horses asses of some kind on all the
groups. I just ignore *them*. Not the whole group.
It's like "John Smith". I think he's a horses ass,
but I don't try to tell him where to go, or others to
avoid him. I just lets the chips fall where they may.
Most people don't need me to help them decide
who is a horses ass, and who is not.
It becomes fairly obvious with the passage of time.
:/

This is purely cheap ground luncheon loaf... IE: bologna
Radio reception is radio reception. It does not matter
if one is a ham, or SWL, or whatever. The rules do not
change due to the type of service being received.
I almost never worry about power handling. Most of
my antennas will take way more power than I would
ever use. It's rarely even a consideration.
What is "ability to hear"? It's basically the same thing
as S/N ratio. In this regard, there is no difference
what type of service is received, S/N ratio is equally
important.

> Read these Posts here on Rec.Radio.Shortwave about

> # 1 - SWL Longwire -by- John Doty

> * Actually, a fixed matching transformer can dramatically
> reduce the wild swings in antenna efficiency that a coax
> fed wire antenna exhibits.

But! that will rarely effect the S/N ratio on the shortwave
bands. Like Roy said, if you can disconnect the antenna,
and the background noise noticeably drops , you have
plenty of signal. Adding a better match will rarely
increase the S/N ratio on HF, because the desired signal
and the undesired noise increase at an equal level.
You have pumped up the S meter readings, but you
have not improved the actual S/N ratio.
When I use my large multi band dipoles for SW reception
on 49 meters, do you think I bother with a tuner?
Nope.. Total waste of time being I already have way
more signal than I would ever need even if looking into
a large mismatch.

> .
> # 2 - Low Noise Antenna Connection -by- J

> the electrical and electronic gadgets you and your
> neighbors have.

I can't argue with this. But trust me, hams are no different
than SWL's when it comes to trying to reduce local noise
pickup. This is just common sense, and not a practice
only used by SWL's. :/
> .
> # 3 - Grounding Is Key To Good Reception

Now, this part here is just plain ole horse manure.
Grounding is not a "key" to good reception, unless you
are using an antenna that requires a ground connection
in order to complete the antenna.
Or the grounding is to further decouple the feed line
from the antenna. But you don't require a ground
to decouple a feed line. It's just one method commonly
used with random length antennas fed with a coax
feed line.
None of my wire antennas require a ground connection
as they are complete antennas unto themselves.
Ground can actually be a source of noise in many
cases.

To sum, some make a mountain out of a molehill. :/
Richard Clarks simple solution of just adding more wire
to the whip on the radio is likely to work just as well
as anything proposed so far. If local noise is a
problem, then he might consider feeding an outside
wire with a decoupled feedline.
Anything further than that is likely S meter pumping
overkill.

Just my two cents worth...
The moisture from the septic field won't hurt and it might help a
little.
The chain link fence is unlikely to be of any benefit and may be a
potential nuscience but it is unlikely there is anything you can do
about it. Until the mesh gets close enough to form a screen or the
lengths of components approach resonance it is likely to be invisible.
In my way of thinking the distance from the edge of the septic field
to the middle of it is insignificant.

Even if you don't damage the septic field you and everyone else
concerned about it will worry forever. Don't go there.

Four feet of metal mast in the ground sounds like an awful chore. I
think I would try less. If I drive anything it is usually a ground rod
and mount to that.

Use 1-1/2 inch fence staples to pin the radials to the ground and you
will be amazed at how well everything works! I tie the radials to the
ground rod with a stainless hose clamp, low cost & works fine.

"N",

Don't know too many 'Hams' would would take 50 Feet
of common Speaker Wire and tie-a-knot at 30 Feet and
then split the two Wires in the remaining 20 Feet and
use the thing as a "Stealth" Dipole Antenna with their
Transmitter -but- a Shortwave Radio Listener (SWL)
can do that and have a very practical SWL Antenna
to use with many 'portable' AM&FM Shortwave Radios.

What, exactly, do you mean by "the inductance of a solid disk"? How do you connect to the disk? Are your connection points on opposite ends of a diameter across the disk, or along its axis from the center of one face to the center of the face on the opposite side -- or perhaps some other connection? With a wire (formed into any shape), it's reasonable to assume it's the inductance measured between the two ends of the wire. For a disk, it's not obvious to me.

Cheers,
Tom

Well, sure, but what does transmitting have to do with
anything? We are not talking about transmitting.
We are talking about receiving, "or at least I am", and
the rules do not change when you vary the frequency a
few mhz.
And there are more than one ways to skin a cat with a
given piece of wire. If I had a portable that normally used
a whip antenna for SW, I would be much more likely to
take that zip cord and split it totally apart to make a
single 100 ft wire. I would simply clip it onto the whip.
I bet my version would be the better performer of the
two, low bands for sure. But this has nothing to do
with what I'm listening to. If I'm listening on a ham rig,
and I'm not transmitting, I'm a SWL the same as anyone
else. :/
And most certainly so if I'm listening to a broadcast band
like 31m, or whatever. Do you think I play by different
rules than you if we are both listening to 31m at the same
time?
I hope not... :/
Sure, you can make a quite decent and usable SWL
antenna from nothing but a piece of wire, or zip cord.
But that is not a requirement to be a ®real SWL.
How would you like to try listening to 19m DX on my
tri-band yagi, which is still close enough to 20m, to
give pretty danged good performance and some F/B?

With that, why would I want to use a zip cord antenna?
It boggles the mind... :/
And I'm talking receive, not transmit. We'll pretend the
mike and keyer have been superglued to a tango-

uniform status.
But I guess being I'd rather use my full size yagi and
have a bit of F/B ratio, which improves S/N ratio, which
is the whole purpose of this topic, I'm not a ®real SWL..
Chortle.. :/
You two guys kill me... You really do.

Uh.. I know where to buy wire.. :/

>
> "n" - practically speaking {in practice} there is a
> difference between between hams and swls ~ RHF

No, there isn't. Not when it comes to receiving.
To propose otherwise is just ludicrous.
I listen to all the same bands you do at some
time or another. I was a rabid SWL when I was in
jr. high school. That was nearly 40 years ago.
I started DXing AM-BC when I was 8 years old
and got my first mighty six transister radio for my
birthday.
It's the main reason I'm a ham now. Just a natural
progression... In other words, I might have been
born yesterday, but not last night. :/

Actually, this is a total misconception.

Download EZNEC or MMANA-GAL. Plugin the figures for a 1/4 wave physical antenna "loaded" to 1/2 wave, examine the radiation pattern ...

Now, do the same for a full 1/2 wave physical length antenna and examine the pattern ...

But then, I am sure you suspected, you can't take a 2 ft. antenna and electrically resonate it to some other physical length, and have it preform as the full physical length version ... if this were possible, everyone would have little one inch antennas on their rigs ...

Simply a pipe dream ...

The same antenna which transmits the MOST EFFICIENT signal possible, will also receive the signal the MOST EFFICIENTLY (given measuring parameters remain the same for both modes, i.e., T/R) ... smaller gauge components with far less power ratings can be used for receiving antennas--that is the most important difference, and actually, the only important one(s.)

However, I can see how some would come the the conclusion(s) you have. In cheap receivers, you really don't know what ohm impedance the antenna jack REALLY is. It may say 50 ohms and be 100, 200 ... 500 etc. Least, that has been my experience ... when you get into professional gear, costing thousands, they can take the time and aim for accuracy.

I am taking it, you mean when it is used as a radiating element in the antennas' construction. Such as a few charts which can be found around which predict the inductance of a wire radiating element -- I have never seen, either software or charts/tables/formulas, to predict such ... perhaps EZNEC or MMANA-GAL could be used for such a purpose--I honestly don't know ... Roy would know ... perhaps Cecil is aware of something?

Or, do you mean something else?

> the feed point.

Nicely is rather a broad term ...

And, if I am running 1KW+, or even multi-kilowatts, and the guy on the other end is doing the same--we can communicate "nicely" on very poor antennas ...

However, if I am running 5 watts, and the other guy is also, a properly constructed antenna which has been designed around efficiency and most desirable radiation pattern, along with having a correct impedance and is matched EXACTLY to the equipment, and such is done without a lossy "matchbox" or inefficient matching method--these would be of paramount importance.

Physics, as much as math, is an EXACT science ... antennas are NOT in realm of "art" (gray areas, open to interpretation, is a matter of personal opinion, etc.), there is but one "best" antenna for any given distance, terrain, pattern, etc.

Well, consider me a "different type of ham." In that, I always construct my antennas to receive the best signal for the application at hand, ALWAYS--transmitting is only a secondary consideration. As, I have never found an antenna which has been found to receive the most efficiently fail to do so in xmit mode. Given both xmitter and receiver have the same input impedances ...

I do, frequently, see hams adjust the antenna, and its' type, for the xmitter--and the best readings which can be obtained in that mode. I pay far more attention to how the antenna receives ... I can always crank up power on this end, should I ever find it necessary--I don't know what the guys capabilities on the other end is/are ...

If that were true then the BIG boys on 160m would have no need for
tall vertical transmitting antennas and traveling wave (Beverage)
receive antennas. They could just use one or the other for both
transmitting and receiving, but they don't. That's because one is
better for transmitting and one is better for receiving.

efficiency is only one measure of antenna performance. high efficiency is
not always better. so while my 100' high inverted L's may be very
efficient, they are not as directive as my 600' long beverages and the
polarization is different, so sometimes when it is noisy listening on the
inverted L's it is nice and quiet listening on the Beverages.

Yeah but we don't care about transmitting goofball, we care about
receiving and so that statement "A random wire (e.g. inverted L)
transmits nicely if you use a tuner at the feed point" by Dave is
relevant where you are not.

>better for transmitting and one is better for receiving.

Let's not confuse "efficiency" (in the standard sense of
power-radiated vs. power-input) vs. "best for the particular purpose".

In the case of 160, you want high electrical efficiency you can get
from your transmitting antenna. This allows your signal to be as
strong as possible at the other end, so that you can be heard over the
band's high background noise level.

For receiving antennas on 160, electrical efficiency is a good deal
less important, because even an inefficient antenna will pick up
enough RF will pick up enough signal to bring the band background
noise level well up above the receiver's own internal noise. Once
you've got this much RF, adding more will simply raise both the
desired signal and the noise by the same ratio - net effect is no gain
in signal intelligibility.

The Beverage antenna is quite inefficient, but its relatively high
directivity makes it useful as a top-band receive antenna. Although
it's relatively insensitive to signals coming from the desired
direction, it's even *more* insensitive to signals and noise coming
from other directions - and thus it deliver a higher signal-to-noise
ratio than a less directional (but more efficient) antenna.

Hence, the Beverage is less efficient than (e.g.) a monopole, but may
do a better job as a receive antenna.

"Random" implies otherwise. Instead of a 9:1 UnUn, imagine one of these
at the feed point:

http://www.mfjenterprises.com/Product.php?productid=MFJ-927

I enjoy playing with these kind of things. So I got a license to
transmit. Some call that "elitist", I call it self-indulgent.

Source record: 18948

Hello all,
I presently have an 80m dipole fed with about 50 feet of coax. I also have a 40m dipole fed with 50 feet of coax at the same height. If I was to replace the coax on the 80m dipole with open wire feeder and used it on 40m, would it have more gain than the coax fed 40m dipole? Also, would it receive better?
Cheers.

I don't believe that.

Simply because, in the last 30+ years, I have NEVER seen ANYTHING get any better--or, at least those things which are in the realm of things influenced by politics, legislation produced by politicians, or for that matter, ANYTHING done by politicians!

They are there because of their desire for either money, power, or both. They support a shadow government solely for what benefits they, their family and friends get from the individuals in this elite group. Although, the above would be impossible to prove at this date; I believe a through awareness and study of the direction "things" constantly seem to be going in leaves one with no other possible conclusion(s) ...

>

Well, examine a mechanical tuning fork. They are cut to an exact
physical length for resonance, the are very sharp tuning. Now, it would
be possible to "lengthen" such a tuning fork with some coil of material,
or portion of a turn of material. There is a reason for this; as,
although it could be done, it would not be as efficient as one cut to
the exact length; plus, you would induce a high probability of increased
harmonics as a freq(s) which the fork was not created to induce ...
there are exact equivalents in the electrical world of RF ...

As you point out, physical length resonance is NOT a requirement ... it
is simply "best" ...

John Smith,

OK then what is a 'matchbox' in :
* a poorly designed transmitting antenna,
* a mismatched transmitting antenna,
* a non-physically resonate transmitting antenna,

Consider the 'matchbox' to be one element
in the RF Energy Radiating System :
Feed-Line + 'matchbox' + Antenna Element

> the feed point.

A resonate 1/4 wave dipole transmits "nicely" and uses no lossy tuner
... a resonate 1/4 wave vertical monopole, with drooping ground plane,
transmits "nicely", requires no lossy tuner, and is damn near a perfect
match to 50 ohm coax ...

A 1/2 wave version of either of the above produces a superior pattern
and can be matched with either a T-match or gamma-match ... indeed, a

very minimal counterpoise is all which is necessary--and, if things are "perfect", not even that is needed, or simply a choke on they outside of the coax a ~1/4 wave away from feed point. A 5/8 is non-resonate physical length, and even demonstrates a superior pattern (at least on paper and with antenna prediction software ...)

However, in side-by-side comparisons on 10-6-2m antennas I have built, comparing a 5/8 against the 1/2 (construction methods/materials and matching components identical) ... the actual difference, in the real world, must be less than the width of a meter needle in the readings ... or, put simply, I no longer deal with the extra length required of the 5/8 ... your mileage may vary ...

Regards,
JS

I have taken ordinary lamp zip cord, split the two leads apart to for a
1/4 wave dipole and fed the end of the remaining length of zip cord with
a balun to the rig (some zip cord is ~68-72 ohm balanced line, the
mismatch is more than acceptable for field/emergency use.)

Never, say never ... some ham will do it!

It has EVERYTHING to do with it, it is the same communication, both ways, simply in reverse ... like I have stated before, the exact same laws of physics governing the antenna makes it equally acceptable to both transmitting and receiving. The same pattern seen in the signal transmitted will be seen in the signal(s) received.

Your argument is the equivalent to arguing that a car designed to go forward would not be acceptable when backing up ... simply ridiculous!

It would be far more "in the realm of correct" to consider what a matchbox DOES, rather than what it IS--as it is simply some combination of inductive and capacitive components which ALWAYS will induce some form of loss into any system it is inserted into.

However:
*a matchbox will allow you to use a poorly designed/constructed antenna--it will NOT improve the antenna.

*a matchbox will allow you to "match" differing impedances to achieve proper power transfer to the antenna--again, it will NOT improve the efficiency of that antenna, and the power will be "simply lost" (as heat.)

*a matchbox CAN allow you to alter the electrical length of an antenna--physical and electrical lengths are two different animals.

And, this is all-in-a-nut shell; as you realize, a proper education in this field is NOT a trivial thing.

That said, I frequently carry a cheap portable with me on trips and launch a longwire into a tree, etc., find acceptable signals and enjoy listening ... or else, just grab the SW stations audio from the net ... being an old-timer, the first is more enjoyable, for me.

JS

5736. transmission lines and SWR and fractional wave antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-28 04:48:21 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <c59c52f3-035b-451d-868d-852346d75d21@y1g2000pra.googlegroups.com>
Source record: 18860

When measuring the SWR of a transmission line we can find a length
that is resonant. Or in other words the current is of an exact
sinusoidal form and thus the basis of SWR. When we apply the same
principles to a radiator
we cannot assume a perfect sinusoidal wave because of the field
generated outside the radiator where a degradation of amplitude
depends not only on the generated fields but also the length of the
radiator i.e a thin radiator. Thus one can see that a fractional wave
antenna if reflected as generally assumed cannot possibly be 1:1 for a
wavelength as per a perfect reflection as could or would be seen from
a transmississsion line.
The above not only shows that a transmission line is a closed circuit
as is a fractional wavelength antenna where the current travels on the
inside of the radiator and where the transmission line has current
flow on the inside of the
outer skin (brading) The antenna compendium states that an assumption
is made with MoM programs that an assumption is made that current in a
radiator is sinusoidal where as we all know that the current degrades
in aplitude dependent on radiator length. It should be seen that when
we use the term SWR we are looking at two different things, a
transmission line which is not radiating(ignoring leakage) but still
a closed circuit and a radiator that is radiating but with a non
sinusoidal current which is contrary to the assumptions made for MoM
style radiator programs. Thus it should be seen that any radiator is a
closed circuit with continuous leakage in current levels dependent on
its length via accountability for all four fouces present..

The theoretical gain of a dish is expressed as (9.87 times D-squared) / (wavelength-squared), where D is the dish diameter. If you have a 3 meter dish and you're working 10m, I calculate the gain as less than unity. Ref: http://en.wikipedia.org/wiki/Parabolic_antenna

Even then, the efficiency of the dish is assumed to be 100% -- which it never is. One limitation is the effectiveness of illuminating the entire surface of the dish uniformly. How can you do that at HF? You need a compact illuminator at the focal point of the dish but HF doesn't lend itself to such gyrations.

I think you should not consider a dish for HF. It works only for wavelengths that are small, compared to the dish size. Don't fight the math.

That is simply ridiculous, as I stated, in any properly designed antenna, with the proper pattern to achieve the points in question, and able to handle xmitter power, and is the MOST efficient for the purpose at hand will be EQUALLY efficient in both transmitting and receiving ...

On 160m, I have ALWAYS used the same antenna to transmit as to receive ...

What I stated is ABSOLUTELY TRUE ... and, there is but one truth possible here. And, certainly, in the situation you stated above, a discrepancy (imbalance) has been, absolutely, induced, as one antenna will out preform the other, have a different pattern, etc.

However, a beverage would NOT be my first choice for a transmitting antenna! And, certainly, there is no comparison over the directionality difference (i.e., patterns) between these two antennas!

You ridiculous fool. You are the most complete brain dead example of a sub-human which has ever been presented to me ...

Receiving is EQUALLY as important as the transmitting element in the above. Or, to explain it to the necessary point, for a mental midget, such as yourself: "If the signal being transmitted is low power, or there are bad conditions, and, perhaps, the guy is in Australia, I'd better have the "best" antenna possible. However, if I am receiving the "50,000 watt atmosphere burner", 50 miles away, a rusty coat-hanger, most likely, would work ..."

However, you mileage may vary with you "magical antenna logic!" <grin>

You hit me as a guy attempting to pass off "magical physics" to kindergarten-ers; but then, even that is, most likely, a challenge for you ... sad, so very, very sad ... :-(

plonk ...

The "Method of Moments" (MOM) makes no assumptions about
current distribution on a radiator; it computes the current distribution.
The radiated field is then calculated based on the current distribution.

> > Feed-Line + 'matchbox' + Antenna Element
>
- - i want to know - iane ~ RHF
- - .

- It would be far more "in the realm of correct" to
- consider what a matchbox DOES, rather than
- what it IS--as it is simply some combination
- of inductive and capacitive components which
- ALWAYS will induce some form of loss into
- any system it is inserted into.

Yeah - Once it is 'placed' in the "System" the MatchBox
becomes part of the "System" and becomes one of the
loses within the "System"

- However:
- *a matchbox will allow you to use a poorly designed/
- constructed antenna--it will NOT improve the antenna.

Now -if- That is True : Then Why Us The MatchBox
within an RF Energy Radiating System ?

- *a matchbox will allow you to "match" differing
- impedances to achieve proper power transfer to
- the antenna--again, it will NOT improve the
- efficiency of that antenna, and the power will be
- "simply lost" (as heat.)

So you are say that a MatchBox will not improve
the ERP of an RF Energy Radiating System ?
And that the Receiving Station will not hear you
'better' when the MatchBox is properly used with
the RF Energy Radiating System ?

- *a matchbox CAN allow you to alter the electrical
- length of an antenna--physical and electrical lengths
- are two different animals.

Electrical Characteristics = 'apparent electrical length'

- And, this is all-in-a-nut shell;

- as you realize, a proper education
- in this field is NOT a trivial thing.

A proper education in 'any' field is not a trivial thing.
And that education can take many forms : formal
practical, vocational {life time of work} and avocation
{life time hobby}

- That said, I frequently carry a cheap portable with me on trips and
- launch a longwire into a tree, etc., find acceptable signals and
enjoy
- listening ... or else, just grab the SW stations audio from the
net ...
- being an old-timer, the first is more enjoyable, for me.
-
- Regards,
- JS

being an old timer myself - i still find simply listening
to the radio to be enjoyable ~ RHF

Actually, the ONLY reason to use a matchbox is that the antenna is less
than optimal for the freq(s) in question, end-of-story. However,
multi-band operation and simply having to cover a wide swath of
frequencies makes this the logical way to go, a matchbox ... in an ideal
situation, a matchbox would be avoided.

>
> Now -if- That is True : Then Why Us The MatchBox
> within an RF Energy Radiating System ?
>

There is nothing magical about a transmitting antenna, like I stated
earlier, the exact same physics govern that antenna in receive or xmit
modes. The matchbox allows you to achieve "maximum POOR performance"
from the POOR antenna ...

> ...
> So you are say that a MatchBox will not improve
> the ERP of an RF Energy Radiating System ?
> And that the Receiving Station will not hear you
> 'better' when the MatchBox is properly used with
> the RF Energy Radiating System ?
> ...

I said NO such thing, indeed, I stated the EXACT opposite, it allows
maximum power transfer to the antenna, however, the losses in the POOR
antenna are now increased due to the losses in the matchbox--as heat.
And, no problems which exist in the POOR antenna have been rectified,
they are just masked ...

> ...
> Electrical Characteristics = 'apparent electrical length'
> ...

As I stated before, physical length need not be related to electrical
length, however, in the most efficient design possible, they WILL be ...
and that is only considering maximum transfer of power to the antenna,
not, necessarily, the ether--and, that is NOT necessarily related to a

desirable pattern of radiation of that power from the POOR antenna--the patten, IMHO, is governed, mainly, by antenna length and shape, however, some designs actually can cheat this, at least a bit.

> - And, this is all-in-a-nut shell;
>
> - as you realize, a proper education
> - in this field is NOT a trivial thing.
> ...

> being an old timer myself - i still find simply listening

> .
> .

As I stated before, a complete explanation/understanding of all factors involved defies a simple explanation ... as, if that were possible, no one would spend years in college, they could attend a week or a month and come away an expert.

And, my field is computer science, this is all just a hobby with me. The little knowledge which I have assembled has been done over the course of years, even decades. I am hear to find out just "how deep this rabbit hole goes ..."

Regards,
JS

- Your argument is the equivalent to arguing that
- a car designed to go forward would not be
- acceptable when backing up ...
- simply ridiculous!
-
- Regards,
- JS

JS -think-about-it-

IF 'by-design' the Car is in-fact designed
to go "Only" Forward :
* It may 'only' have Forward Gears and
a Transmission that has NO Reverse.
* No Rear Window
* No Rear Mirror
NOT So Ridiculous ~ RHF
http://www.prweb.com/prfiles/2006/10/17/452347/mormonmeteor72.jpg
.
Just an Example of "Single Focus" Thinking :
Optimizing Your Results For One Purpose.

Sort of what Shortwave Radio Listeners (SWL)
do when they consider how they are going to
Design, Build and Use an Antenna for the
Hobby of Shortwave Radio Listening (SWLing)

Yes as you have pointed out : There is a Greater
Boby of Knowledge and Practicum Out There
That Could Be Considered and Used -but- The
Shortwave Listener (SWL) often is 'selective' in

what they consider and use to achieve their
specific limited goals.

It Has To Do With "Level-of-Involvement" :
* Many/Most Amateur Radio Operators {Hams}
have the well earn knowledge and experience
to function 'like' an Auto Mechanic -wrt- Cars
* * Hams at their best are Advocates of the
Technology [Practicers of The Craft]
* Many/Most Shortwave Radio Listeners (SWLs)
simply enjoy a level of knowledge and experience
to function 'like' a Car Driver -wrt- Cars
* * SWLs at their best are Hobbyists Enjoyers
of the Technology [Users of the Technology]
TBL : Both are Need -and- Both are Different

~ RHF

hi

does anyone know of a make/model verticle antenna i can buy for
around 1296, just need to work the local repeaters

i am in a good high area so something simple would do , but oddly
enough i can't seem to find much for that band

already have some spare hardline run up to the roof

any help appreciate thanks

5747. dipole feed to leg

Message-ID: <m-0E4AB7.08184028122008@news.optonline.net>
Source record: 18871

hi

In the case of a center fed dipole, typically you want the
feedline lets say coax, drooping downwards

in a case where you might not be able to do this and need the feeding
coax to b closer and more parrallel to one of the legs .....

i realize that this will make the dipole more inefficient and
distort the pattern...

but how do you even roughly calculate that??

thanks

The advantage of a physical height (antenna length) between 180 and 215 degrees (see previous post regarding the magic number being around 195 degrees) is improved take-off angle and reduced skywave-groundwave interaction, not dramatic nearfield voltage increases.

That looks like junk,KC8QJP . You're better off sticking to the bogus tax returns or are you still in prison for that?

FORMAL DISCIPLINARY HEARING-KATHLEEN R. LEE
Chairman Woods noted that Kathleen Lee was issued CPA certificate 36,525 on July 15, 1998. The hearing was to consider disciplinary action against Ms. Lee's CPA certificate pursuant to Ohio Revised Code section 4701.16(A)(5), conviction of a felony under the laws of any state or of the United States. Ms. Lee was convicted in the United States District Court, Northern District of Ohio of five counts of Aiding & Assisting in Filing False Tax Returns, a violation of 26 USC 7206(2), on June 12, 2000. Ms. Lee did not appear at the hearing. The Board agreed to deliberate the disciplinary action in a later executive session.
Action taken.
Kathleen R. Lee, CPA 4701.16(A)(5)-Convicted of aiding & assisting in filing of false tax returns. CPA certificate revoked.

Thank you so much for your input
The URL that you directed me to does not show the restrictions and
assumptions that apply
and we all know that radiation is filled with such things some of
which are not supportable.
A case in point is how reflection is shown upon the belts that
surround the earth which is shown as a curved
like particle rejection where at the same time the URL shows a
straight line reflection.
I do not accept this theory but do accept that a dish is covered with
particles at rest which will repell impinging particles with spin.
I would also point out that the design shown in the URL is based
around an antenna that is broardside where the phase angle comes into
play.
This is distinctly different to a radiator with axial flow that does
not depend on phase change as with planar design reflectors that
evolve solely around inter inductive coupling. As far as the math is
concerned I am starting a a premise that is supported by marthematics
just as one would expand all of Maxwells laws to be solely limited to
those of Ampere where I used an extended Gauss insteas all of which
are based around Newton where the term
(=) is the support for equilibrium or symmetry and where the theory of
radiation of sound and light being of a wave nature is thourouly
debunked in favor of particles.
Never the less your comments are interesting but also symbolic of the
fact that the laws of radiation sghould be thourouly reviewed in the
light of present day findings such that incorrect notions such as the
formation of waves are re examined.

Yes it does but as always one must review the basis on which formula
is formed and conditions expressed
```

One of these conditions is that current flow is sinusoidal which
cannot be true because of leakage (radiation)
per unit length of the radiator. If on compares the current flow of a
full wave radiatior to a fractional wave
current flow this becomes very obvious especially when either of them
is compared to a true sino soidal curve
Cheers Frank

> Cheers.

In theory the full wave should be good for a couple of extra DB
broadside. So yes, you would have a little gain broadside to the
wire. But you would have less gain in the other directions.
Receiving would be reciprocal. Gain broadside, less gain in the
other directions.
Whether it's any better is up to the directions you are working
at the time. Could be slightly better. Could be slightly worse..
There is no free lunch.
If it were me.. I'd stick with what you have unless you have a real
need for gain broadside to the wire. Also, 2 DB is barely a 1/2
S unit on the average receiver. Just barely worth the trouble.
I have used extended dipoles at times, but I prefer the EDZ over
the full wave dipole. IE: .64 wave per leg, instead of .50 wave per
leg. You will show appx 3 db gain broadside over the dipole with
the EDZ. Even 3 db is not earthshaking, but it is an effective
doubling of power in the two directions broadside to the wire.
You have to decide if more gain broadside is worth less gain
in the other directions.
On the low bands like 80/40, I prefer to be fairly omnidirectional
as the people I work are usually in all directions.
Also, a 1/2 wave dipole fed with coax is one of the most efficient
systems you can use. :)
If I run anything else, it would usually be a turnstile. That's what
I've been using on 80m the past few years. But I'm just running
a regular dipole on 40m.

Hello to all,

The context is this: We are discuting about capacitance hats.. It seems that the name is confusing, since it adds inductance instead of capacitance to an antenna.

So, since a solid disk adds inductance (the resonnant freq of the antenna drops), we are looking for a formula to evaluate that inductance (and then inductive reactance)..

BTW, why don't we use the name 'inductive hat'...??

adding capacitance also lowers the resonant frequency. remember, the
capacitive hat is not adding capacitance in series with the feedpoint, it is
adding to the self capacitance and capacitance to the ground.

ah yes, don't forget the diamagnetic part... maybe your antenna didn't work
because the wire mesh you used was ferromagnetic instead of diamagnetic so
it didn't have the layer of magical mystery levitating neutrinos. or maybe
you turned it upside down so all the neutrinos ran out of the dish.

None of the conditions assume current (distribution) on a radiator is
sinusoidal. It can be anything, not even remotely sinusoidal, and
frequently has discontinuities (such as a "unit step function" in the
case of a shunt fed, gamma matched, grounded tower, for example).

The theory behind the "Moment method", in the case of NEC 2,
is in the public domain, and available here:

http://www.nec2.org/other/nec2prt1.pdf

Frank
What I am pointing out that radiation theory is based on assumpotions
and theories
both of which are built upon to the present day. Examples are the
extrapolations with respect to light
consisting of waves (arrived at be fore Maxwells correction to his
laws) and the assumption of reflection from an open ended antenna
which has now become an erronious science of its own.
Such assumptions and theories are thourly embrased in the NEC format
in the same way the yagi was embraced as a close approximation
of antenna theory. A point to note besides Krauss';s study of helical
antennas there have been two additional studies of the gain provided
(Hayward was one plus another based on NEC) All of the gain figures
arrived at were different by a disturbing amount a problem that has
not been resolved. Actualy one of these studies showed that a "cupped
" reflector provided far superior gains over other style reflectors.

I am not saying that NEC is grossly inaccurate but only that the solutions provided are not precise., Using just one example radiation at present is presumed to provide many waves along a conductor purely on the bases that current is reflected from the antenna end and progresses along the same path that it arrived. This error alone has allowed many assumptions and erronious theories to be expanded.
Cheers
Art

I was pretty primitive in the early days. :/
Not much money, so I made do with some weird stuff.
Here is my "radio room" when I was in the 7th, 8th grade
or so. Probably about 1971. The "room" is the closet in
my bedroom..
http://home.comcast.net/~nm5k/r2.jpg
The radio was a philco portable. Covered 4-12 mhz.
No BFO.. So... I would use the white AM radio sitting
behind it as a BFO. :/ Not the most fun in the world,
being neither radio was the most stable things around..
But it would let me listen to CW and SSB with tuning
tweaks every once in a while. Well, maybe more than
once in a while.. :(
The other white AM radio to the left was more for the
clock, and I used the radio in it for local AM listening
most of the time.
The antenna was just a random wire strung out the
back window.
The contraption in the foreground was the first transmitter
I built. It was a single 6V6 run off line voltage for the B+.
Did maybe 5-10 watts I guess.. 40m, and I had two
crystals. Look at my advanced scotch tape coil forming
construction. :/
The chassis was WW2 Navy issue.. The circuit from the
1949 ARRL handbook. Yes, it actually worked.. :)
I later rebuilt it using a transformer, and a bit more power.
I used it as my first novice transmitter for a good while.
By that time, I had a Hammarlund HQ-110 for a receiver.
But as a SWL, I listened to half a zillion stations just with
that little philco portable and about 50 feet of wire hooked

to it.
Spent half a fortune "to me back then" on IRC's to get
faster QSL replies. You can see a RAI card on the wall.
They sent me magazines for about 20 years after that card..
I still got color RAI magazines into the late 80's at least..
For many years, I used to get a Christmas card from Radio
Havana.. Every year.. Then like the RAI mags, they finally
quit coming.
I used to get some real nice glossy color magazines from
China back in those days. :/ The FBI probably thought I
was some kind of communist being I used to get so much
mail from them...

Let me make this clear once and foir all. Ferromagnetic material
provides for retension of energy via
the hysterysis effect amoung other things. This detracts from energy
required for the Foucault current
which is required for the application of spin to particles. This is
not to say that some vestiges of the
eddy current is not present but it does suggest a typically reduced
radiation field.
As far as a dish reflecter is concerned that has been built around the
necessity of a focal point in the phase changing aproach provided by
inductive interactive elements and does not follow the same aproach
required by the addition of the levitating weak force known as the
Foucalt current

Art, the current distribution along even the shortest (fractional wavelength), constant OD radiator also is ~sinusoidal.

Currrent always is near zero at the open end of a linear radiator of every physical length. The shape of the current wave formed along a very short radiator appears to be very close to triangular. But in fact that "triangular" current distribution is just a very short section of a sinusoidal waveform.

N.B. that MoM programs show exactly this for radiators that are very short in terms of electrical wavelengths. This also is proven mathematically in the antenna engineering textbooks of Kraus, Balanis, Johnson & Jasik, etc etc.

ah, so your old theory with the magical levitating diamagnetic neutrinos was
wrong and now you are using a phase change approach (whatever that may be)
and inductive interactions (which i thought you disliked because that is
part of how a Yagi-Uda array works). if the magical levitating diamagnetic
neutrinos is good enough for one antenna, why isn't it good enough for this
one??? or are you admitting you are totally wrong?

David,
you are building an auguement on sand like "have you stopped beating
your wife?"
You can traverse the world with a steel antenna using less than a watt
with the same message
as a Kw from a huge antenna. The only difference is that one system
provides less samples
of communication for the ear bone requires to decifer. This being
under ideal conditions which are rarely the situation.
I have never disliked the Yagi antenna but I refuse to belief that the
gains enjoyed are absolute because they ignore
the implications of the weak force or eddy currents.They are easily
built. They give close approximations in terms of gain
But the gains supplied do not equate in absolute terms upon which
science rests.

O.K. have it your way. At the end of a radiator voltage is a maximum
as current is zero
ie the curves of current and current crosses each other. We can then
use the absolute standard
equatiion of E = I R. Using this formula for understanding conditions
at the end of a radiator
we can state that E, I and R equals zero ala a non closed circuit.
Kraus used four travelling waves in his analysis of the helical
antenna an analysis that was not corrobarated by
following examiners or the application of the NEC (MoM) programs where
disturbing differences was never resolved.
You introduce wavelength as if it was a standard without considering
the velocity factor and where a transmission line analogy
does not satisfy a helical antenna because of slow wave created in a
similar way to cavitation as explored by Bernoulle
or by the addition of sharp corners encountered by current flow

As far as what has been proven in text books they are only reflect the conditions placed on the problem but also assumption of correct theory applied.
This is why history shows the evolution of science is a series of broken theories whose value is measured by their resistance to attack over time.
I would remind you that the metric of time has NOT stopped. But as I stated earlier you can have it your way without objection from me

now this i must hear... how do you get from steel antennas to samples in the
ear bone? is my ear bone a digital sampler now? does it somehow sample
your magical levitating diamagnetic neutrinos straight out of the aether?
There must be more to this radio stuff than meets the eye if the ear is
involved now! how does that work for transmitting video, does it change how
the eye bone works also?

>I have never disliked the Yagi antenna but I refuse to belief that the

I have no problem with the way Roy presented the material ... and, I believe there is high probability that you are correct, some people are more concerned with how material is delivered rather than the material itself ... I don't do well in those situations. And, I wish to accept no responsibility in having to participate, it makes for too much work.

I simply wish to cut to the heart and deliver the material in a manner I prefer, I am sure there some who prefer the importance of material over the presentation ...

Source record: 18752

A little OT for this group, but I figure you guys are the experts!

I've got a boat, it has an VHF FM Car Radio with a car aerial. The first problem is that there is no ground plane, the boat is GRP. It is also lying horizontally, it is too long to be vertical.

I want to replace the aerial something a bit more suitable. Modern cars seem to have much shorter aerials, so is there a coil involved?

Any suggestions on making or buying a replacement?

BTW, the radio has a DIN antenna socket, so 150 Ohms I think?

As a talking head there is no need for you to understand the nuances
of science.
You, like Richard have survived most of your life on unproven data so
I can understand your need to question
whether there is a need for the corrected data that science provides.
This echoes the statement for removing the patent office as "all
possible discoveries have been realized"
Remember what I told you in the past. Free speech is O.K. but the
downside is that it also shows who and what manner of man you actually
are.
From my viewpoint what you have stated so far has only reduced your
credability with respect to radiation and increased the assumption
that you are nothing but a talking head, a trail you started years ago
when denying the feasability of introducing static law with those of
Maxwell where your basis was again just words without scientific

backing.

Absolutely, and at some point I must trust the reader has the resources
to extrapolate; otherwise, all postings would soon turn in to the
length, depth and completeness of a college textbook ...

For example, an antenna is a two lane road, running in both
directions(T/R), the same parameters which allow it to be the best
choice for transmitting, also are in action when that same antenna
"plucks" its' signals from the ether ... something I have pointed out in
multiple ways, multiple times ...

The average person must hear, read, study the same material six times
before "learning" it. And, an instructor once pointed out to me, not
all people respond to the same method, personality, mode-of-presentation
as another or others ... so, he pointed out the importance of gathering
data from multiple sources until the "epiphany" is realized ...

IME,Most car radios are sensitive and selective enough to pull in local
stations with only a short wire hanging out of the antenna socket. I've
routinely checked them out on the bench,and just stuffed a piece of
hookup wire in the antenna jack,works fine.
Maybe you could just run a wire up some vertical-surface of the boat?

There *IS* a ground plane-The water. When the boat is in the water,the
water itself is the ground plane.

I see you are ready to go to extraordinary lengths to justify your statements or propose "special cases" which are only correct in extreme circumstances of very limited parameters--this is all fine, however, carry on without me ...

Again, it is as true as when I originally stated it, the same antenna, its efficiency, fitness-for-purpose, pattern delivered, etc. will work the same, both forward (transmitting), or in reverse (receiving.) I am sure there exists the possiblily of "breaking" or "orchastrating" the antenna physics to bring about a special case or cases ... no practical use I have yet seen has required this.

Many hams wish to think themselves "special" because of their hobby, now you have brought me to the realization that there is the equivalent in the SWL'ers hobby ... to me, it just looks like one of my other hobbies, like tropical fish, for example.

I see what you mean, the disk DOES contain inductive reactance (I don't even know how to begin to compute its' value, however), and, as per your post, the capacitive reactance to ground is an important point to consider.

I hope he posts back, with more definition, he posed a question to catch my interest; although, you are best to provide us with real information.

Sorry, when replying to Cecil, I missed this post ... thanks for posting back. Yes, in the scope of my knowledge, it WOULD, indeed, add inductive reactance to the antenna, however, as Cecil seemed to imply, the effect of the capacitive reactance, you are also adding with the disk, overwhelms the inductive ... however, Cecils' input will be the correct one; consider mine a guess.

As I previously stated, works nicely on paper/software; in real life, I have not been able to construct an antenna which demonstrates an advantage to justify the difficulty of dealing with the extra length. Now, a 2m on down, why not "toss it on", just in case?

Now, when loading a 1/4 wave physical length antenna to a 1/2 wave electrical length, I DO see an advantage, increased radiation resistance, minimal counterpoise required, etc. Even when taking into consideration the losses added by the coil ...

Exactly correct. EZNEC (including demo) users can get a good illustration of this by looking at the pattern from the example file Cardioid.ez which consists of two identical elements with perfect spacing and perfectly ratioed base currents. Notice that the front/back ratio is about 35 dB (dropping to about 31 dB with more segments for more accurate results), while it should be essentially infinite. The small back lobe is caused by modification of the current distribution on the two elements caused by mutual coupling -- although the base currents are perfectly equal in magnitude and 90 degrees out of phase, the fields from the two elements aren't, due to their having slightly different current distributions. When I first saw this back lobe with perfectly ratioed base currents, I searched through the program code looking for what I was certain was a bug. I finally realized that the result was correct and that the lobe was caused by the altered current distribution which the program had correctly calculated. For more about this, see http://eznec.com/Amateur/Articles/Current_Dist.pdf.

The assumption of sinusoidal current distribution is strictly true only with straight, isolated conductors which are infinitely thin, although it's a reasonably good assumption in many other cases. Mathematical analyses of antennas done before computers were pretty much limited to cases where sinusoidal distribution was assumed, because a more accurate determination of current distribution was virtually impossible to calculate. The ability to determine the actual current distribution is one of the very important advantages of computer analysis.

Yes you are correct but the original equation was E=IR
which preceeds the implication of impedance which is a derivative
of my equation and came about with the addition of A.C. technology.
If the impedance is totally resistive then my statement is not untrue
Now to avoid the nitpicking are you saying that E=IZ cannot be used
for calculations at the end of an antenna and if so" WHY "

Oh, "I get it", you guys just don't get the lack of importance to your point(s!)

Correct match to you rig does NOT affect the antennas efficiency, you would still want the most efficient antenna.

Antenna length does relate to efficiency, and normally you would erect the longest possible for the freqs, and the efficiency of the antenna is improve, if by nothing else, than capture area ... however, you must balance this against the antenna pattern you wish.

The pattern of the antenna, which will be identical in both T/R, is important. Antenna efficiency is important. Match to feedline, and feedline to rig is important.

You seem to feel that s/n ratio is something to pursue, I tell you it is not. This is actually handled in the antenna pattern, you do NOT want the antenna to be receptive in the direction(s) of noise sources nor have it prone to static charges and disturbance ... antenna design is what controls this.

Your main problem is that you wish to separate all the elements out and be able to deal with each one separately--you can't, every added capacitance adds some measurable amount of inductance, every added inductance adds some measurable amount of capacitance.

There is never a case when you wish to decrease antenna efficiency, well, unless you are attempting to construct a dummy load ...

If the antenna is "too sensitive" (efficient), crank your rf gain down a bit to the noise floor ...

However, if I was supporting a poor antennas' use, or selling a poor antenna, lack of attention to efficiency would be my first "selling point!"

Let me repeat, there is NEVER a time a ham or swl'er will want lack of efficiency--they have rf gain controls and other "attenuation boxes" to handle that--you obviously are attempting to confuse antenna efficiency

with another aspect of antennas ... indeed, efficiency can be applied to most aspects of an antenna, i.e., "most efficient length", "most efficient match", "most efficient placement", "most efficient design", "most efficient pattern", etc.--and these CAN all vary as to the antennas intended use ... you can never make one change in antenna design which DOES NOT affect all others--i.e., one change makes many ... it is why EZNEC and MMANA-GAL are so desirable to toy with ... load up the software, make one change, watch it affect all others ... well, most of the time.

Regards,
JS

>
> S.T.W.

Now, to sum that previous post up tightly, and it the hopes you "may get it" THIS TIME ... you NEVER want a less efficient antenna--in the fact that efficiency relates to transferring power to and from the ether. Or, in the case you wish to focus upon, "efficiency = ability to pluck incredibly weak signals from the ether."

Any other argument, is simply to replace a respectable antenna with a dummy load or a partial dummy load; and, is not something which is usually argued against, by sane men ...

It is complicated by multiple currents. Like an open-circuited transmission line, electrical conduction stops at the end of the conductor. Current then becomes a phasor problem.

Collapse of conduction current induces a voltage which combined with the incident voltage almost doubles the total voltage at this spot in many cases. This reverses the direction of current in the conductor. Due to capacitance at his high-voltage spot with the iniverse, displacement current flows into free space from open-circuited antenna ends. It is usually smaller than the conduction current.

I would think if you measure the inductance from the center of one
side of the disk to the cnter of the other side of it would be like a
large number of hair pins in parallel.
I tried building a collinear antenna around this idea with the
vertical part of the antenna a solid piece of CU tubing with the disk
place at .5wl points. The problem was that the disc act as capacity
hat.

If current distribution is calculated correctly as stated then the
answer with respect
to the route taken of the current of a fractional wave antenna should
be available and beyond doubt
as the program is derived from Maxwells laws. The distributed current
should be DC based if current flow is thru the center
of the radiator. As far as the resistance encountered on reverse flow
on the outside of a radiator the figure provided by computor programs
should be rather interesting as I have never encountered in print

suggested figures. In accordance with some engineers the radiation resistance but be stated as the radiation impedance to avoid sniping

You skated over the difference between an open circuit of the
transmission
line compared to the end of an antenna.
The analogy is flawed and will be shown when the resistance in the
center of a radiator is disclosed via the
computor programs. You never did supply the information needed to
justify the values of E,I and R when
the current value crosses the zero line on a graph. You can ofcourse,
declare that none of the given factors
can ever be equal to zero by jumping the datum line !!!!! By the way,
could you state a situation where the
displacement current is LARGER than the conduction current so I may
review it in the light of Newtonian laws?

Remember, the current where a capacitive hat is located in the antenna
(at the end of an element) is relatively low. Adding inductance there
has relatively little effect. On the other hand, that's just where
even small amounts of capacitance have a fairly large effect.

Consider too that if the environment is symmetric, such as with a
vertical over a flat, uniform (or radially symmetrical) ground, with a
top had that's also radially symmetrical, the current in that top hat
will be radial and symmetrical, and will for all practical purposes
cancel out with respect to radiation from the top hat itself.

Look at the change in current distribution along the antenna
conductor, and compare the situation with and without top hats. It
should become immediately obvious what the advantage of a top hat is.
I would certainly call the effect "capacitive" and not "inductive."

It may also be instructive to look up design notes about VLF
transmitting antennas. Very large non-radiating "top hat" structures
are commonly used in them to get reasonable efficiency. I think
you'll be able to find examples of this sort of design from as far
back as a hundred years ago. The folks I've talked with about the

design of one such local antenna system are quite clear about the top wires' role in changing the current distribution in the vertical element, but not contributing directly to the radiation in any significant way.

Adios,
Tom

Powerboat or sail? I recommend a quarter wave for sail, but 5/8 should work on most powerboats. If you can mount atop a metal mast 1/4 wave should easily do the job. I get really good broadcast FM reception on my FT897D from my dual band mobile antenna out on the back deck. For receive-only with good broadcast signals, impedance matching is not that much of a concern. If you're trying to DX, that's another story, involving yagis.

How about a simulation? NEC is happy to handle this sort of
situtation. It's the outside of the coax that you care about as a
radiator; just add a conductor to the model approximating the position
and length of the coax as best you can. If the coax goes all the way
to the ground, that probably makes the model simpler. You can model
it with and without a choke (balun) to try to isolate the coax from
the antenna feedpoint.

I think you will find that if you put a choke balun at the antenna
feedpoint and another one a quarter wavelength back down the line from
that, the feedline will have relatively little effect on the antenna.
You might model the baluns as, say, 500 ohm inductive reactances (or
other inductance, if you know what you'll actually use). In
situations where I've had trouble with a lot of RF induced on a wire
where I didn't want it, I've found resonant chokes to be very
effective: as much inductance as I could reasonably get, paralleled by
some capacitance added on purpose to make it resonant at the operating
frequency.

Cheers,
Tom

Santa left me an FT-10R, which I plan to put on my Shadow Spirit 1100. Nice bulletproof dual band unit with a detachable head, Bluetooth, and a lot of other features.

While I'm deciding where to mount the radio - a Spirit is kind of retro chopper style, not a lot of open space, and whether to go bluetooth or wired for the headset, the antenna could be another issue.

I had originally thought about a 5/8th, but a possible setup might have the antenna have no or little feedline, being directly connected to th e unit.

I also want some sort of compromise between obtrusiveness and performance. I'm willing to put a bugcatcher on the SUV, but aesthetics are more important on the bike.

Dual band 144/440 on a motorcycle...Any suggestions?

JS - You started using 'Car' Analogy; and
I followed through with 'Car' Analogy ~ RHF

To many/most Hobbyists there 'hobbies are simply
"Hobbies" : Some thing that they do in their spare
time to enjoy and pass the time. Most Shortwave
Radio Listeners (SWL) fit into this Category of
Hobbyists.

For some/many Hobbyists there 'hobby' is their true
"Avocation" in-fact for some Their HOBBY is Their
Life : Some thing that They Do All The Time : They
Live and Breath Their Hobby : Many Amateur Radio
Operators {Hams} fit into this Category of HOBBYISTS.
http://www.answers.com/Avocation

This is Why I refer to Amateur Radio as "The Craft" :
The Mastery* of the Body of Knowledge and Practices
related to the Science and Art of Radio Operating.
* All Praise Be To Them That Do.
-but- that is not me : for i remain simply a plain old
shortwave radio listener : who keeps his swling
"k-i-s-a-p" = keep/ing it simply and practical

If some one asks "Where To Buy" :
I tell them 'where to buy'.

If some one asks "How To" {Build It} :
I tell them 'how to' {build it}
They Did Not Ask for "The Theory Behind It"
-and- i don't give them 'the theory behind it'

If some asks "What Do You "Recommend" :
I 'recommend' a something or two and usually
provide a few links as pointers to get them going.

hey it is just my opinion and nothing more - kisap ~ RHF
-ps- JS Yes You Are Right "I Am Extremely Special" ;-}

Thanks for the info. A very interesting link. I have experimented
with NEC models of phased arrays, and found the same problem
with a small back lobe. I followed the procedure in the ARRL
Antenna book, which involved calculating the elements in a 2 X 2
complex Z matrix, for a 2 element phased dipole array. The
results appeared to be very good, but I never actually built it.

Art wrote:
"could you state a situation where the displacement current is LARGER than the conduction current so I may review it in the light of Newtonian laws?"

I have difficulty in imagining current between the plates of a capacitor exceeding the current through the capacitor`s leads.

Values of voltages and currents anywhere along an antenna primarily depend on the impedance of the antenna at that point and then are dictated by the phasors of the incident and reflected totals at the same point. Arnold B. Bailey in Fig. 7-28 on page 368 of "TV And Other Receiving Antennas" shows current distribution on a half-wave dipole which smoothly varies from zero at its ends to maximum at its center.

Experience shows that a quarter-wave back from a maximum impedance point, a minimum impedance point is created by incident and reflected phasors.

Best regards, Richard Harrison, KB5WZI

Hello, Roy, and while the above is certainly correct, you're probably wasting your time. Many folks like to fashion their own "reasonable" explanations even when they're completely off track (should I mention the CFA again?). Of course they're always right and it's the rest of the world who's wrong. Certain folks on this ng appear to be in constant need of validation. Persons without some knowledge of the underlying physics and applied math are destined to reach the wrong conclusions IMO. Of course that's not going to stop some from building a CFA because as we all know it's the standard comms antenna used at the Groom Lake facility to keep in touch with Klaatu. Sincerely, and 73s from N4GGO,

<<thanks very much surprized to hear ya say it might have little
effect, my gut told me as the feed wire got anywhere near one of the

legs something would go really wrong either pattern , or swr or
etc etc

i guess the feedline wouldn't go to ground per say at least not
physically thou i guess the chassies of the rigs are technically
grounded

I wasn't worried about (thou it's important) my 'antenna'
disturbing the feedline, more the other way aroound due to proxmity,
so i wonder if your comments regarding chokes were with respect to
that meaning i wouldn't think chokes would make the feedline
less 'visable' to the dipole leg then again maybe i am wrong
on that

really appreciate your taking the time to post thanks much and
happy holidays

Mike,
Not being familiar with that bike, and also probably not having the same 'aesthetic' values, what I would consider 'workable' probably isn't going to be the same as your 'workable'. So, take this for what it's worth.

Does your bike have a fairing? What are the chances of mounting an antenna on that, if it does have one? Is it fiberglass? How about just running a strap to the frame? Considering the size of 'groundplane' required by a typical VHF/UHF antenna, a bike isn't all that small. Getting that antenna 'connected' to the frame ought'a do just fine.

The idea is certainly do-able, so I think the 'aesthetic' value is the 'catch'. That's up to you...

I enjoy sending intelligence from point A to point B without wires. I enjoy making spikes (not Xmas trees) on my FSH-313. My work involves UHF FM transmitters of between 10 mW and 250 mW. These need to go 300-500 feet (flawlessly). This is very similar to my hobby (what I enjoy). I can't believe they pay me to do this.

ML,
Any/every thing around an antenna is going to affect it's radiation pattern to some extent, including feed lines. How much affect those things have is the practical aspect of that. The 'classical' radiation patterns, typically shown, are just that 'classical', best case possibilities. The more 'mundane'(?) patterns are usually never going to be the same, and in most cases, not really all that important, sort of. It would be nice to be able to predict things by using the 'classical' patterns, but just not a very practical thing to count on. Depends a lot on which bands you're talking about too. 'Directional' is typically more important for the higher bands than the lower ones, propagation and all that 'stuff'. Which isn't to say that you shouldn't worry about it, just only to a 'practical' extent. The easiest/hardest solution is to just move the thing till it's 'right' for you.
Yeah, I know, sort of a totally useless post, right? Oh well...

Nigel M, former G1NDM wrote:
"Any suggestions on making or buying a replacement?"

I`ve installed coaxial antennas at VHF which worked well on boats. They consist of a quarter-wave rod insulated and mounted on a quarter-wave cylindrical skirt which surrounds the coax feedline. The match is good. There are no radials to poke eyes. The assembly makes a half-wave vertical antenna.

At 100 MHz, the wavelength is about 3 meters so the overall length of an FM broafcast antenna should be about 1.5 meters. You likely can find such an antenna for sale ready made. If not, it is not difficult to make your own. The folded dipole made from TV twinlead also works well but presents a 300-ohm impedance and may not work as well with your DIN connector. It also requires suspension. The coaxial antenna usually is equipped with a small mounting pipe surrounding the coax.

Best regards, Richard Harrison, KB5WZI

In simple terms, when the standing-wave current has
a zero amplitude at a current node, none of the energy
is in the magnetic field and all of the energy is in
the electric field. That's why a voltage maximum appears
at a current minimum. When the current equals zero, the
virtual impedance, E/I, is infinite.

This is essentially what happens at the end of a dipole
or monopole or open-circuit stub. The characteristic
impedance of a #14 wire 30 feet above ground is very
close to 600 ohms. Given that Z0, we can treat a dipole
element as a lossy transmission line and calculate the
voltage at the end of the dipole element.

If we model a 1/4WL 600 ohm open-circuit stub with
EZNEC and adjust the resistivity to 0.0000021 ohm-m
to simulate the radiation resistance of a dipole
wire, the feedpoint impedance of the stub is 35 ohms
and conditions on the lossy stub are very close to
the conditions on a dipole element.

At the end of the radiator you state the energy is transfered to the
field
so I would imagine there is zero skin effect at that point and the
chain of
skin effect is still present on the outside of the radiator, this
because a full period has not yet elapsed
This equates to a displacement current across the capacitance gap
(plates) between
the outside and the inside of the radiator which is the only current
route available
when the capacitor field expires. Note that this energy is released
prior to the end of the current flow period
because of the absence of the skin effect at that time.
Cecil I am examining all the holy cows that pervade the science of
radiation

as it is universally accepted that radiation is not fully understood,
thus the many hats!
At the moment I see no mechanism that supports the capacitor field to
expire in the direction of incoming current
prior to the completion of the forward period.

The "capacitive" field is the *electric* field which is
at a *maximum* amplitude at the tip of a dipole. It is
the magnetic (inductive) field that is close to zero
at the tip of a dipole.

Cecil
I still am looking for an explanation that prevents current flow thru
the center.
I recognise that the common thinking is to accept reflection but I
fail to see
how that can happen so I can follow up with the numbers.
The capacitor is limited with respect to the energy that it can retain
so what happens when that
limit is reached and the forward period has not come to an end? Yes,
the common thinking
is that the current changes direction to oppose the forward moving
current as with a reflection
where the eddy current in the reverse direction cancels the eddy
current moving in the other direction.
It is here that I am looking for a mechanism that justifies this
reasoning of reflection so I can begin to dispel the
closed circuit aproach as seen with a full wave radiator in
equilibrium
Best regards
Art
Art
but I am looking for actual proof

There is a sudden flash as energy jumps the gap between the plates.

The energy a capacitor can store expressed in joules is equal to its capacitance in microfarads times the voltage (squared) across its plates divided by two million.

For a fixed capacitor, the only vatiable is the voltage. So, the greater the voltage across the capacitor the greater the energy it stores. The only limit is the breakdown voltage.

Best regards, Richard Harrison, KB5WZI

So one acknowledges the presence of a capacitor at the end of a
radiator
So now we determine the capacitance and the voltage withstand
together
with what comprises as a capacitor at the end of a radiator to relate
to
which way the current flows.
The question with respect to current flow is still present and
unanswered
despite all of the manouvaring the face the question head on.
If the past means anything this subject could go to a 1000 posts with
neither
a modicom of science to bolster the talk

Well, being a logical person, I would ask what mechanism
of physics keeps the forward current from flowing through
the center to start with? Why doesn't the forward current
flow through the center and the reflected current flow
back on the surface?

Whatever that mechanism is, it seems logical to conclude
that it might also prevent reflected current from flowing
back through the center.

If we put a signal generator at each end of a wire,
which current flows on the outside and which flows on
the inside?

Art wrote:
"Yes, the common thinking is that current changes direction to oppose the forward moving current as with a reflection where the eddy current moving in the reverse direction cancels the eddy current moving in the other direction."

Transformers are laminated to reduce eddy current core losses.

Reverse currents on a transmission line or on an antenna are usually called the reflected current.

Reflections are caused by discontinuities in the path of the EM wave.

In the case of an open circuit, the reflection coefficient is infinite and the incident and reflected waves have the same magnitude and phase. The voltage at the discontinuity is thus doubled. See Terman`s 1955 opus page 89. But, the current goes to zero as conduction ends at the open circuit. No energy is lost in the open circuit. It is just concentrated in the electric field as the magnetic field loses its energy.

Best regards, Richard Harrison, KB5WZI

Let's use IEEE definitions to avoid confusion. A "capacitor"
is a physical component that exhibits capacitance. Capacitance
can be exhibited without the existence of a physical lumped
component. At the end of a radiator, we would have a
distributed capacitance, not *a* lumped capacitor. And
actually, it is not only at the end since it is "distributed".
In fact, an antenna element can be modeled as a distributed
RLC network where the R includes all "losses" including radiation.

If what you say is true, I am wasting my time. But I believe there's a more diverse group of readers:

1. The people who already already know and understand what I'm explaining;
2. The people who think they know and understand what I'm explaining, but don't, and won't change their minds no matter what I write; and
3. The people who are willing to read and understand what I write, and learn from it or at least think about it.

Just like medical triage, only one of the three groups can be helped, in this case #3. It's for those folks that I take the time to post. I hear from them in various ways from time to time, so I know they're out there. And I'm glad to pass along to them what I've learned, when I can.

Art wrote:
"At the end of the radiator you state the energy is transfered to the field so I would imagine there is zero skin effect at that point and the chain of skin effect es still present on the outside of the radiator, this is because the full period has not elapsed."

It will elapse as it does in every period so that the higher resistance at RF will take its toll as predicted.

Because of skin effect, hollow conducting pipes exhibit almost as much conducting ability as solid rods of the same material. This creates a market for aluminum tubes as radiating elements and Copperweld wire in antennas. High-powered transmitters use silver-plated coiled pipes to carry distilled water to cool their final amplifiers. The space within the coiled pipes carries no significant RF. RF energy does not flow out on the surface of a conductor and return in the conducting material within the conductor in ordinary circumstances, although phase lag within a conductor increases as penetration depth increases.

Best regards, Richard Harrison, KB5WZI

The gain would be different, but that's because the pattern would
change, you would have more gain broadside but at the expense of less
gain elsewhere in the pattern.

You would very definitely need a tuner, but that's not a disadvantage.

I am a strong strong proponent of the "all band doublet", with a tuner
what you describe would be a useful antenna on all ham bands shorter
than 80M. And with a little cleverness (tie the two conductors
together and feed it like a vertical against ground with a tuner) it
will be usable on 160M too.

Roy,
That is exactly how I felt when I declared that the addition of a
radiator
to a Gaussian statics field under the application of a time varying
field equates to the
mathematics of Maxwells laws. Nobody, including you, showed an error
in that thinking.
Another person provided the mathematics that proved my point again ,
nobody could disprove it.

Anybody can view the book by Ramo and co "Fields and waves in
communication Engineering"
where in Appendix 11 where the a sample method of tackling the proof
is available in it's entirety.
Some could even read the chapter on radiastrion which spells out
problems with the existing aproach.
Remember when the presence of particles on a radiator is determined by
any person well versed in mathematics
and science then the true vehicle of communication is thus determined.
All of the above is directly
applicable to the stance in words only that you have expressed above
but.....no action
It blows my mind when people desert from mathematics and science in
efforts to prevent change.
T,here is no evidence what so ever that Newton's laws applicable in
this case has now been discarded in science
and that evidence destroys the notion of communication and the
emmission of light can be attributed to a field wave form
instead of the particles outlined in Gaussian law.

No Cecil. We are at the end of the radiator and there is no eddy
currents in front.
Ther apparently is a gap between the outside of the radiator end which
some see as a capacitor
(tho I see nothing that suggests that as yet) If one accepts a
capacitor as distributed then I will go along with that
but that alone cannot stop the flow of current.

Yes, Cecil caught me not paying attention. At an open circuit, the impedance is infinite but the coefficient of reflection is the ratio of the voltage of the reflected wave to the voltage of the incident wave. As both have the same phase and magnitude, value of the reflection coefficient for an open circuit is 1.0, not infinity.

Here's why antenna efficiency is important for transmitting but not for HF receiving.

First, the definition of efficiency: For a transmitting antenna, it's the fraction of the power applied which is radiated. The remainder is turned into heat. For receiving, it's the ratio of the power which is delivered to the receiver to the power which could be delivered to the receiver if the antenna had no loss. The efficiency of a given antenna is the same when transmitting and receiving. Sometimes people use "efficiency" to mean other things -- this is the meaning of the term in all antenna literature and texts.

Consider this communications system:

transmitter - antenna - propagation path - antenna - receiver - listener

A receiver unavoidably adds noise to the received signal. So if no noise is injected in the propagation path, the signal/noise ratio is the ratio of the signal entering the receiver to the noise created by the receiver's input circuitry. This is generally the case at VHF and above.

When receiver noise dominates, as above, increasing the receive antenna's efficiency increases the signal arriving at the receiver, so the signal/noise ratio improves. This allows you to hear the signal better. But it only works for VHF and above.

HF is a different story. At HF, there's a lot of atmospheric noise (injected in the "propagation path" part of the system), and unless the receive antenna and receiver are exceptionally bad, the atmospheric noise is much greater than the noise created by the receiver. I mentioned a simple test in my last posting, to see whether this is the case -- just disconnect the antenna. If the noise level drops, atmospheric noise dominates. It's not hard to make a receiver that atmospheric noise will dominate with a 3 foot whip antenna at HF. So at HF where atmospheric noise dominates, the signal/noise ratio is the ratio of the signal entering the receiver to the atmospheric noise entering the receiver. Compare this to the situation described above for higher frequencies.

Now let's see what happens when we improve the efficiency of an HF receiving antenna. Because both the signal and the dominant noise come from locations in front of (that is, on the transmit side of) the antenna, improving the efficiency of the antenna makes both the signal and noise greater in the same proportion when they arrive at the

receiver. There's no improvement at all in the signal/noise ratio. The effect is the same as turning up the receiver volume control. The only way you can improve the signal/noise ratio is to somehow favor one over the other, such as by making the antenna directional. And an inefficient, directional antenna like a Beverage or small loop will nearly always enable you to hear better in some directions than an efficient, nondirectional antenna because directionality helps and inefficiency doesn't hurt.

How about transmit antenna efficiency?

The signal strength from the transmit antenna is proportional to the antenna's efficiency. (It also depends on other things, but I'm just talking about efficiency here.) So if the efficiency of the transmit antenna increases from, say, 33% to 66%, the power levels of the signals at the receive antenna and the receiver double, and there's no change to the received noise, on either HF or VHF and above. So improving the transmit antenna efficiency always improves the signal/noise ratio at the receiver, in this case by 3 dB.

That's why you can hear bunches of HF stations with a very inefficient antenna, but they won't hear you if you try to transmit using that same antenna -- it's because the noise is injected into the system between you. And it's likely that you'll be able to hear stations just as well with the very inefficient antenna as with a much larger, efficient one.

Assumes that you are omniscient and people can only learn
facts from you.

Roy, I don't think that any assumption of your omniscience
is warranted. Is it impossible that you are wrong about
anything in the world? Is the reason that you absolutely
refuse to engage in a rational discussion of the role of
interference in antenna systems because you might be proven
to be wrong and also learn something new in the process?

I have given some thought your statement; I mean, it just strikes me as so bizarre, I ignored it.

S/N ratio will NOT improve with an antennas efficiency, indeed, it will increase lineally. The more efficient the antenna (sensitive) the more-efficient it will be at receiving "on frequency noise" from even greater distances. However, a poor antenna may be "efficiently receiving" harmonic related noise which a cheap receiver may have inadequate rejection against ... indeed, there are many "side-scenerios" which are possible.

You seem to wish for a very highly efficient/sensitive antenna which will do some sort of noise rejection (or, for some reason, have, in error, given antenna physics this magical/mystical ability(s.)) However, "that/those antenna(s) only exists in science fiction, at least at this date."

Surely, you have poor design which is subject to static noise and/or poor antenna pattern which has noise sources within that pattern. And, of course, if one operates an omni antenna, noise is a given, unless you live in a very remote part of the world, or are running a dummy-load as an antenna ...

Date: 2008-12-30 02:42:47 UTC
From: ml <m@di.net>
Message-ID: <m-46D957.21424729122008@news.optonline.net>
Source record: 18737

after my building changed to a new tv antenna and master amp
seems i am giving alot of tvi on strangly enough 2m

also some tvi from 10m too never did before

my antenna is physically pretty close to the antenna (thou it also
was previsiously)

for an experiment i was thinking about just making a coaxial stub
for 2m to see if that would 'notch ' out the interference

and using a T connector putting it just before the master amp (which
i think is just amplifing my 2m signal and mixing w/the tv channels
and or overloading the tv's)

should the stub be 1/4w on 2m or would say 1/2w be 'better'?

i'd cut it for the center of 2m

tnx

That is correct, except only the people who misunderstand surface wave propagation are being misled.

> earth curvature.

Radiation at one degree will indeed reach the ionosphere. But not the radiation propagating as a surface wave, as I'll show.

The field launched at very low angles contacts the ground and in doing so, induces a current into it. This extracts power from the wave as it propagates. The result is that the surface wave field is attenuated quite rapidly with distance. At AM broadcast frequencies, it propagates far enough to be useful for local broadcasting, but it doesn't reach the ionosphere. If it did, fading (due to surface and sky wave interference at distant points) would be a much more serious problem for broadcasters than it is. As you go higher in frequency, the attenuation becomes greater, so the surface wave propagates even less distance before dropping below the noise level. No measurable fraction of it ever goes anywhere near far enough to reach the ionosphere.

> The theoretical elevation patterns shown in my plots don't exist very
> far from the antenna, but they are a closer to reality over real
> ground than those shown by NEC and NEC-2 for an infinite distance over
> the same ground, and assumed also to exist close to the radiator.

NEC (NEC-2 and NEC-4) does a very good job of showing surface wave ("ground wave") field strength. It uses the same calculation method as used by the FCC and, I understand that NEC modeling results are now being accepted by the FCC in lieu of measurement for AM broadcast proof of performance.

> The results obtained using NEC-4 to calculate the groundwave field
> intensity within the useful daytime coverage areas of AM broadcast
> stations give much better correlation to the measured fields, and to
> the methodology of using the theoretical pattern with the FCC's MW
> propagation curves.

NEC-2 and NEC-4 give virtually identical results for both ground and sky wave propagated fields. The results below were done using EZNEC Pro with the double precision NEC-4 calculating engine. Results using the double precision NEC-2 engine were different by less than 0.1 dB.

Here are some numerical values to illustrate what happens to the ground wave field(*). Two antennas are analyzed, one at 1 MHz and the other at 7 MHz. Each is 1/4 wavelength high with effectively a zero loss ground system. The 1 MHz antenna is 7 inches in diameter, the 7 MHz antenna one inch diameter. (Diameter in this range makes no significant difference.) Ground is "average" -- 5 mS/m conductivity, dielectric constant of 13. Data are for elevation angles of zero, one, and two degrees, to distances of 50 miles. In that distance range, the difference between flat and curved Earth is negligible. The reported field strengths are in dBi for easy comparison; to convert to mV/m, use

mV/m = 1000 / Distance(m) * Sqrt(30 * Power(w)) * 10 ^ (dBi / 20)

dBi is a comparison to the field from an isotropic antenna with the same input power, measured at the same distance. So if the attenuation of all parts of the field is the same with distance (in other words, if the pattern is the same shape at all distances), the dBi field strength will be the same at all distances.

First, the results. Field intensities are shown at various distances from the antenna. These are the entire field, including surface wave. View with a fixed-width font.

Field strengths, dBi, are under each elevation angle:

		-- Elev angle --		
Freq(MHz)	Dist(mi)	0 deg	1 deg	2 deg
1	inf	-inf	-11.8	-6.8
1	1	4.0	3.6	3.4
1	10	-2.8	-5.0	-4.6
1	50	-18.7	-12.6	-7.0
7	inf	-inf	-18.1	-12.7
7	1	-15.8	-15.4	-12.2
7	10	-36.7	-18.3	-12.8
7	50	-50.8	-18.1	-12.7

The two lines with "inf" distance are sky wave only, that is, the field is evaluated at a great enough distance that the ground wave has decayed to effectively zero. This is what you'll see with EZNEC's Far Field analysis, or with NEC if you don't include the ground wave. The difference between these and the entries at other distances represents the contribution of the ground wave at those distances.

As Richard has observed, the field strength is zero at zero elevation angle and long distances. At the AM broadcast frequency of 1 MHz, there's still the useful field strength of -18.7 dBi at the surface at 50 miles (even though the field strength is 20 dB greater -- not shown -- at an elevation angle of 20 degrees). Notice, though, how the zero degree field relative field strength continues getting smaller with distance. Fortunately for the broadcasters, the surface wave component doesn't detach itself from the Earth and head for the ionosphere as the Earth curves away, but follows the curvature of the Earth. This allows broadcasting beyond the horizon without ionospheric skip, and prevents fading from the ground wave alone. It doesn't reach the ionosphere as Richard has claimed.

The ground wave contribution is noticeable at one and two degrees also. But look at what happens with distance (at 1 MHz). At 50 miles, the ground wave contribution at those angles is hardly noticeable, as you can see by comparing the dBi field strength at that distance with the dBi field strength at an infinite distance. Interestingly, the dBi field strength is shown to be very slightly lower at 50 miles than at an infinite distance. This might be due to some of the power in the surface wave at 50 miles being transferred to the sky wave at greater distances, or it might be due to small calculation errors. But the differences are slight, indicating that no significant ground wave energy remains at 50 miles at elevation angles of 1 and 2 degrees. There's no noticeable ground wave energy at higher angles at or beyond 50 miles, and very little at closer distances.

An analysis of the 7 MHz antenna shows the same thing, except that the ground wave decays faster as expected. At that frequency, the one and two degree field strengths have reached their sky wave-only values at 10 miles -- indicating essentially full decay of the ground wave -- , and the zero degree field strength is less than -50 dBi at 50 miles.

The _ARRL Antenna Book_ propagation chapter devotes only one paragraph to surface wave propagation(*). It summarizes that "The surface wave is of little value in amateur communication, except possibly at 1.8 MHz." Analysis which concludes that the surface wave plays a role in ionospheric skip is erroneous and leads to conclusions which are simply and demonstrably not true. Ground wave field strength is of interest at HF only for communicating with stations within a few miles, and at MF with stations within a few tens of miles.

(*) Technically, the surface wave is only one kind or component of a ground wave, as explained in the _ARRL Antenna Book_. However, NEC uses "ground wave" to mean the wave in contact with the ground, which some others call the surface wave. This discussion is about the wave in

contact with the ground, for which I've used "ground wave" and "surface wave" pretty much interchangeably. There's a good discussion of surface wave propagation in Terman's _Radio Engineering_ as well as other references.

Probably receiving amplifier overload.

Antennas usually couple more tightly side by side than they do end to end where they reside in each other`s nulls. If the TV antenna is horizintally polarized while your transmitting antenna is vertically polarized. that should greatly decrease coupling between the antennas. Maybe distance between the two antennas can be maximized. Maybe the new TV antenna has a feedline defect allowing the line to become part of the receiving antenna. Its coax should prevent noise pickup not cause it. Maybe careful adjusting cross-polarization of the antennas, or a combination of cures will fix your problem. I hope you are lucky.

Best regards, Richard Harrison, KB5WZI

It's purely because of where the dominant noise comes from, more specifically whether it gets into the system before or after the antenna. Atmospheric noise gets greater as you go down in frequency. At VHF and above, it's less than receiver noise, so receiver noise dominates and masks whatever atmospheric noise there might be. At HF and below, it's usually greater than receiver noise, so atmospheric noise masks the receiver noise. Obviously there's no precise line, so somewhere typically near the upper end of HF either one might dominate, depending on conditions, antenna, and receiver.

The noise you get from your VHF radio when you turn down the squelch is receiver noise. You can prove it by disconnecting the antenna and noticing that the noise doesn't change. Disconnect the antenna from an HF receiver and the noise will drop, because it's coming from the other side of the antenna.

This might help:
<http://en.wikipedia.org/wiki/Atmospheric_noise>

If you extend the red line showing man made noise, at greater than
about 30Mhz, the man made noise (ignition noise, motor noise, etc)
predominates over atmospheric noise.

Usually a 1/4 wave open stub, or a half wave shorted stub...

I used to use 1/4 wave stubs to attenuate strong local TV signals from a masthead amp that was primarily used for weaker signals. The frequency of the wanted vs interferring signal were a nice 2:1 relationship so I was kind of lucky. I used 75r coax and just chopped it to about .82VF and it actually worked first time.

I'd suspect though that the problem is more likely to be fundamental overload. Of course it cant hurt to try.

Both a 1/4 wave open and 1/2 wave short stub present a low Z to the tuned frequency, or if you like "shorts it out", If however the wanted pass freqency is an odd multiple (1/4 wave) or an even multiple (1/2 wave) then you end up attentuating that as well.

Cheers Bob VK2YQA

OK, a 3 meter dish at 160m:

Numerator is 9.87 times 3-squared = 88.83
Denominator is 160-squared = 25600

The quotient is the nominal power gain = 0.00347

In technical terms, this equals a fart in a windstorm.

BTW, to validate the formula for a practical dish, plug in the values for the same 3-meter dish, but use C-band TVRO freqs around 4 GHz. Take the log of the quotient, multiply by 10 and you get close the customary 40dB gain associated with those backyard beauties. (I just got rid of mine this year; the new owner wants to try EME at 1.2 GHz.)

In my last couple of postings, I was lumping man-made and atmospheric noise together as "atmospheric noise". Both enter the system between the transmit and receive antenna, so improving the receive antenna efficiency won't help the ratio of signal to either atmospheric or man made noise. The referenced graph doesn't show receiver noise at all, which dominates at VHF and above.

It can be useful, however, to distinguish between atmospheric noise and *local* man-made noise, since the latter can sometimes be reduced by using techniques such as feedline decoupling and using horizontally polarized antennas.

Well, this is probably a suitable time to offer my thanks for taking
the time to explain how things work (and to correct my screwups).
Thanks much. I suspect that the time and effort are not a major
problem. It's tolerating the nonsense that passes as a substitute for
intelligence that bothers me. It's difficult to argue with
unsubstantiated illogic and one-line simulated cleverness.

I do the same in alt.internet.wireless.
<http://groups.google.com/groups/profile?hl=en&enc_user=bLQuYRAAAACBvdjA7WBXQw3w3fqwxHRj>
Hmmm... there should be much more dating back to about 1987.

One of my tag lines is:
"I judge people by their willingness and ability to learn".
I have no problem with those that disagree with me. It's easy enough
to make the distinction between disagreement and learning failure. If
they understand both sides of a debate, they're doing just fine.
Otherwise, you're debating against dogma and bias, with little home of
having anyone change their opinion.

I'm mostly in #3. I read, learn, sometime ask, occasionally comment,
and save some postings for reference. I'm fairly well informed in my
areas of expertise, but am seriously lacking in others. Antennas is
one of those where I'm lacking. Sometimes you go over my head, which
is not a problem. I can dig out the details later. However, some
URL's, references, and additional reading pointers would be helpful.
Overall, your postings are all useful, interesting, and well worth
reading.

As for the diversity of the readers, it's probably all over the map. You have the difficult problem of trying to write something that is understandable by every knowledge level from complete beginner to professional antenna designer. It's easy if you know something about the person with whom your discussing some topic, but very different if you're dealing with an anonymous visitor.

Thanks again.

Open quarter wave, shorted half wave. I don't know which is better.
Remember to shorten the stub length by the velocity factor of the coax.

I had a similar problem years ago on a Navy ship. Nearby taxi radios around
154 MHz overloaded the antenna amp. I bought a "Midband Trap" from a TV
shop downtown which fixed things. It went inline and attenuated those
non-TV signals between (approx) 120 - 170 MHz. It was only a few dollars
from one of the well-known TV reception equipment makers, Channel Master, I
think.

Unfortunately, I haven't found it from any familiar names, but I did locate
this page http://www.microwavefilter.com/pdffiles/pg27.pdf. The 3367-A/I,
3367-B/G, 3367-C/G and 3367-C/H should all do what you need for 2m
suppression. Prices unknown.

... and this page: http://www.atvresearch.com/overstk.pdf Find their
number 5KMT-A/I-TX Midband Trap. A clearance sale bargain if they still
have any left.

Here's a single-frequency tunable notch;
http://www.microwavefilter.com/pdffiles/pg28.pdf.

Good luck.

5878. Re: Vertical Monopole Radiation Characteristics

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-30 12:11:23 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <bd171585-9bfc-463f-9a9e-5082f567779b@i20g2000prf.googlegroups.com>
Source record: 18602

Roy Lewallen's post of Dec 29, 9:45 pm generally supports the points I have been writing about.

But two observations are due:

> Fortunately for the broadcasters, the surface wave component
> doesn't detach itself from the Earth and head for the ionosphere
> as the Earth curves away, but follows the curvature of the Earth.
> This allows broadcasting beyond the horizon without ionospheric
> skip, and prevents fading from the ground wave alone. It doesn't
> reach the ionosphere as Richard has claimed.

The last sentence above is incorrect in that I made no such claim. My post stated only that radiation from elevation angles as small as one degree will reach the ionosophere. See the paste below.

"But that isn't the case -- the relative field over real ground at low elevation angles close to the vertical radiator can be very high, and will continue onward to produce a long-range skywave. Even radiation at an elevation angle of one degree will reach the ionosphere, due to earth curvature."

A low elevation angle does not include zero degrees (the horizontal plane).

>The reported field strengths are in dBi for easy comparison; ...

The term "dBi" is not a unit of field strength. Field strength is a voltage existing between two points in space typically one meter apart, and is expressed in terms of that voltage with respect to that distance, as in volts/meter (V/m).

Field strengths can be compared using decibels, but such comparisons are referenced to the field strength shown in standard form. For example, a field strength of 1,000 µV/m may be expressed as 60 dBµV/m.

>
> Best regards, Richard Harrison, KB5WZI

<< big thanks to all those that replied

I agree it is prob 'overload' but thought perhaps notching might
work, i already have some really good multistage tvi filters but
wanted to be ready with a notch for when the building lets me into
the closet in case that is not enough.

My thought was to try and make stubs cause they are 'cheep' but
those links to the commercial site were pretty cool

wasn't sure the difference between the single stop unit and the one
with 2 stops (past the obvious)

my thoughts would be that either wont effect the other
frequencies as a stub might (2nd 3rd harmonic?)

Currently have 2 2m antennas Rich, once is a arrow 2/440 jpole
and it is about middle of the antenna towards it's left side
about 2 ft or so away

directly in front of it is a M2 eggbeater rather omni pattern

it's about 3-4ft away so the tv antenna is looking right at it

I don't really have any place to move the antennas to other than
some sort of compramise like moving the antenna towards the floor
wich then the elevator room would block me in at least 1 compas

direction and losing the altitude would of course loose me the distant repeaters using one of those floor mounts which i already have actually

question
perhaps putting the 2m antenna higher than the tvi antenna might do the trick ? the jpole has no radials the eggbeater does so i am guessing the eggbeater might offer less downward radation? and therefore offer less tvi if higher than the tv ant?

thanks

Sal
Are you using formula based on phasing i.e. has a focal point?
If so that is not applicable to CP (circular polarisation) antennas
One is a broardside radiator and the other is a axial or end fire
radiator.
BIG BIG difference. If you study the use of reflectors with helix
antennas you will see that all
reflectors used are straight sided whether as a flat plate, cupped or
as in one instance
conical for the length of the antenna. The parabala is based on inter
inductive coupling
of a dipole so the parabola reflects at maximum current amplitude.,
The helix reflector is not based on
coupling but the true mechanical impact of particles which is vastly
different. It is wonderful when
you use formulas but it is always best to initial perform the
calculation from first principles
to ensure that the formula is applicable where you intend to use it
I have removed my dish and have replaced it with a sheath an aproach
that has already been used for CP
radiators.

5882. How to estimate groundwave distance?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-30 14:50:22 UTC
From: Eric <answer.to.newsgroup@nospam.com>
Message-ID: <71ckl4drdn9qgos1cqnlih5d7h84fupq3q@4ax.com>
Source record: 18606

Can anyone tell me the best way to estimate the groundwave coverage I'm likely to get on 75 meters?

I tried R. J. Edwards (G4FGQ] GRNDWAV3.EXE, answered all the questions about type of terrain, frequency, power output, and antenna efficiency, and got an answer of around 50 miles for an S-5 signal at the other end.

(With the noise level around here, S-5 is about the minimum to shoot for around here...)

And yet, in the real world, I am lucky to be able to establish reliable contact with another station that's a bit less than 10 miles away.

We are both using horizontal NVIS antennas, which I guess aren't as good for groundwave as vertical antennas. In any case I have no idea what to put in to G4FGQ's program for "antenna efficiency". I tried 25 percent and got the 50 miles for S-5, then reduced antenna efficiency to 10 percent and got 40 miles for S-5... still well below what I am seeing in the real world.

I switched to a terrain type of "City blocks, roads, streets, industrial areas, rivers" and got 32 miles for S-5, then switched to "Mountainous regions, bare rock, vegetation in valleys" (we do have a few molehills around here that people call mountains) and got 28 miles... still beyond what I'm really seeing.

So, how can I estimate the longest reliable groundwave distance on 75?

Thanks...

> >you are building an auguement on sand like "have you stopped beating
> >your wife?"
>
> well, have you?

Absolutely not!
I am working from first principles starting with the mathematics of
the Gauss/
Maxwell comparison which was mathematically shown on this newsgroup
by Doctor Davis of M.I.T. provided., This clearly shows the connection
of .
particles as opposed to waves with respect to radiation . This is a
confirming proof of my
aproach I have taken with respect to first principles. Nobody but
nobody has pointed out any error in this aproach.,
For years you have asked for the mathematics and now you have it. If
you can't break the
mathematics then you do not have a platform. It has been quite a
while since the math was provided
and no faults have been provided, the silence has been deafining.
It is because of this finding in my work I am forced to proceed via
first principles since our ancient books
follow a contrary aproach

>snip

> you better believe they ignore the weak farce, that is all in your head.

The whole world supports the CERN project which costs billions, which
is based on the existence of the four forces. If you are not aware the
weak force is one of the four stated.

I don't think that a NVIS antenna is a "ground wave" antenna. It works
by sending the signal straight up and bouncing it off the ionosphere
back down covering the area around the antenna.

But you should do better than what your doing if you are using on both
ends a NVIS antenna. It strikes me that maybe the antennas are not at
the right hight to function correctly. Also if only one station is using
a NVIS antenna and the other is using a vertical or dipole that is high
off the ground that could be the problem. Those antennas have a reduced
response to signals coming in from high angles. It is a well known effect.

Consider using vertically polarised antennas because a ground wave is
predominantly vertically polarised. NVIS antennas are usually horizontally
polarised with respect to zero degrees elevation.

> Good luck.

Professionally its often done with a pair of stubs shunting the transmission line with a quarter wavelength of line between their junctions so the shunt low impedance of each appears as a high impedance where the other stub is connected. Sometimes the Q is increased by using resonators with lower loss than co-ax cable (e.g. cavities or helical resonators). The resonant frequencies can be staggered a bit to improve temperature stability.

An interesting homebrew affair that can yield an impressively narrow notch is the bridged 'T' circuit, like http://www.hobby-electronics.info/course/html/ch20s04.html, one of which is explained at http://www.hobby-electronics.info/course/html/ch20s04.html. The temperature stability is only as good as the (lumped) components but using a preset variable resistor allows the loss resistance of the coil to be cancelled out to some extent. For 2m I have used the centre-tapped L version but with the input and output lines tapped into the coil, which preserves more of its Q. It worked well for 'listen through' from a 2m repeater with 600 kHz separation, using separate Tx and Rx antennas.

>
> Thanks...

You need to use verticals if you want to use the ground wave on
the lower bands.
There basically is no ground wave when horizontal. Only a space
wave, which is not likely to go as far.
So in order to use the ground wave on the low bands, you need
to be using a vertical antenna to transmit.
How well that will do depends on the antenna, amount of noise, etc.
50 miles should be a good average, with some times better, maybe
others worse. IE: you will almost always do a lot better in the
winter,
than summer just due to lower noise.
Try it in the daytime. The noise is usually lower, and the ground
wave doesn't care what time it is.. :/ It should always be about
the same no matter what time of day. You lose a lot of ionospheric
clutter in the day, and can get a better idea what the ground
wave is doing. But there is still some skip in the day..
So if you end up working someone 200 miles away, it's
probably *not* via the ground wave. More likely the D layer
or whatever. But on the other hand, if you can work someone
50 miles away, and the signal is the same appx level every
day, day in, day out, it's probably the ground wave.
There could be minor season and moisture changes, but
overall it should stay fairly stable strength.
I know when I ran a 40m dipole at 36 ft, and also had a full size
ground plane with the base at the same height, the difference
in local coverage was drastic. Some times the band conditions
"NVIS" would stretch out, and I would lose the locals that were
across town if I were on the dipole.
But I could switch to the ground plane, and no problem.
In the daytime on 40m, I could often work people way out
west of town in mobiles, that the locals on dipoles wouldn't hear
due to the often long skip and lower signals due to being mobile
and vertical. Some of these were 70-90+ miles away.
I don't know how much of the total was ground wave vs space
wave, vs the ionosphere , but when I would switch to the dipole,
they would drop way down.
The ground plane did put out a pretty decent space wave
being it was elevated. Way better than the same antenna

ground mounted. And it was fairly efficient, which helps
no matter which path it takes.
The lower the frequency, the better the ground wave.
IE: tune AM radio in the daytime. Any station you pick
up that is out of town is coming to you via the ground wave.
With a good radio and antenna, you can receive quite a
distance. IE: from Houston, I can hear Dallas, San Antonio,
even farther, no problem at all. Almost pure ground wave,
and being such, it's easy to null out if needed vs sky wave
which usually comes from multiple paths.
But say take a 10m vertical at 50 ft in the air. The space
wave is the primary path in case of working local.
Not the ground wave like the low frequencies.

We're both using horizontal antennas... his is a dipole up about 25
feet, and mine is an inverted vee that's up about 40 feet in the
center and 10 feet at the ends.

I know that a vertically polarized antenna would work groundwave
better, but we need to be able to maintain reasonably reliable
communications pretty much everywhere within about a 200-mile circle.
We can use 160, 80, and 40 meters to do it, and theoretically we can
use any amount of power up to the legal limit but in reality, as a
practical matter we are limited to 100-200 watts.

There are some in our group who really, REALLY think that the vertical
is the way to go, and I need some debating points. So, if I had a
decent ground-mounted vertical, should I expect to get the ground wave
distances that G4FGQ indicates in his calculation program?

Is there any area / radius that would be covered by a ground-mounted
vertical that wouldn't be covered by an NVIS horizontal (assuming that
we're operating below the critical frequency)? I have always assumed
that by the theory behind NVIS, the answer would be no... NVIS should
cover everything out to a radius well beyond groundwave distance.
But, I suppose we could install NVIS antennas AND verticals and switch
between them to see which one works best at any given time. Does seem
to be a wasted effort but WDIK?

While I'm at it, how do I estimate antenna efficiency? What is the
average range of efficiencies normally seen with a quarter-wave
ground-mounted vertical, with an adequate ground radial system, in
average soil?

> 1 10 -2.8
> 1 50 -18.7

I thought it would interesting to compare the field strength values for these parameters when using the FCC's propagation curves to that which can be calculated using the antenna gains in dBi (not field intensities) stated in the 3rd column above.

Here are the results (fixed font):

Distance to NEC Field
Dist, miles Calculated NEC Field per FCC Curves
1 170.6 mV/m 0.9949 miles
10 7.8 10.25
50 0.25 49.94

Agreement is excellent at 1 and 50 miles, less so at 10 miles.

These are pretty common in the CATV business where they will notch channels
to put their own access channel in place.

It is likely the CATV guy came out and took all the filters out in
preparation for the digital channel changeovers. There ought to be a High
pass filter to cuttoff below channel 2 and likely a notch for VHF
air/commercial?ham energy. They may have also goofed around with a cheap
distribution amp. Many of the good setups would split up and break out
individual channels to peak or attenuate to try to balance the lineup.

Note that radiation from the end of a low dipole is vertically polarized.
Antenna efficiency, and surface wave field strength, can be computed
with NEC.

Why don't you connect together the two terminals of your 'NVIS' thing, drive it with respect to a good earth, and use it as a monopole with a capacity hat? There's a lot of chat going on about those here at the moment, and some of it is correct, like no appreciable HP radiation from a symmetrical horizontal hat. All it really does is to move the radiating part into a higher-current portion of the quarter sine wave.

Given the type of antennas you mentioned with 100 W. If they are facing end
to end,
and, over an average ground, you should expect: 21uV (S7 - 8) at 20 mi, and
14 uV (S6 - 7) at 30 mi. If the antennas are parallel then the signals
will be
10 db weaker. I used NEC for the analysis.

It's a cruiser - it looks like this one, minus the windshield.

http://www.motorcycleminnesota.com/030107/05/05.htm

> Is it fiberglass? How about
> just running a strap to the frame?

The rear fender is steel. I think I'll opt for a small dual bander,
mount the radio on the back of the backrest, the antenna on the fender
and go from there.
Shouldn't be too much loss in the 6 inch piece of coax needed!

Stubs work very well. You should try the single wire stub first.

You'll want good low loss coax. The better, the deeper the notch.

1/4 wave for the middle of the 2 meter band, and open at the end should take out the 2 meter overload.

Anecdotally, I used a single stub during a contest to knock out overload from 40 meters @ over a kilowatt. The antennas were around 50 feet away from each other.

Being a 2 pole circuit, the stubs are quite broad and because they appear
as a shunt capacity or inductance off frequency can cause major VSWR upset.
The other drawback which may be an issue for TV is that they will also notch
out frequencies at 2N+1 (odd multiples).

You really need both. I'd not put in a vertical unless I had a horizontal one also. If I had to choose one, it would be the dipole. But if you can do both, the vertical has it's uses.

> Is there any area / radius that would be covered by a ground-mounted

> between them to see which one works best at any given time.

That is the ticket. I'd done some experiments between the two antennas, using an attenuator and antenna switch. Aside from generalities, which have become "truth" under different circumstances, the antenna that performed best at any given time changed, and not always in the way you thought. Sometimes in mid-QSO.

Too many people think of take off angle as some sort of blob of RF that comes out of the antenna at one place, and not much elsewhere. All antennas radiate at all angles. Some just more at some angles than others. The point of this is that that vertical better be pretty efficient, because what use is a lower angle of radiation if it is putting out less RF than another antenna that even though the other antenna might have a higher take off angle, but have still more power output at the lower angle.

> While I'm at it, how do I estimate antenna efficiency? What is the
> average range of efficiencies normally seen with a quarter-wave
> ground-mounted vertical, with an adequate ground radial system, in
> average soil?

Best way is to use an antenna design program. This would probably be a very good idea if you need to convince your cohorts The big thing is, don't just look at the SWR plots, and don't just look at the antenna patterns. Looking at the bigger picture, it becomes more than just a Ford versus Chevy argument.

Plane wave reflection from a parabola doesn't have a discrete current
maximum, per se. You are not describing an antenna element whose current is
maximum at the feed point, etc, etc.

That was not my intention. I am pointing to the use of a parabola
reflector as used
with a planar design such as a dipole placed at the focal point to
provide the required phase change
for reflection. ala best possible coupling to achiev e desired effect

>
> > The helix reflector is not based on
> > coupling but the true mechanical impact of particles which is vastly
> > different.
>
> Maybe true, maybe not. Irrelevant either way. No 160m helix antennas.
If you review the works of Kraus and written thesis on different types
of helix
design including the addition of multiple studs you will note that
all reflector surface are linear
and where the sheath style reflector provided maximum gain.
Because of the condensed volume of designs based upon equilibrium
top band frequencies as well as broadcast and below frequences are
available
in a rotatable manner for directivity.
By the way my antenna is based on equilibrium
(how many times have I stated that on this newsgroup?)
which ruled out the standard helical design as it is NOT in
equilibrium

>

>

> I did that, it was, and I'm grateful to have your support.

Sal
I don't think you did that
The parabolic reflector
is a design to be used in concert with planar designs only.
I used a parabolic initially for temporary experimental purposes only
as I did not find any data of it's use. As cup style reflectors have
proven gain figures for NON planar axial radiation radiators that
would seem
the obvious way to go at the moment

Are your NVIS antennas oriented the same way, geographically? And are you seeing a nice spike in the signals during the early part of the evening, only to lose them later? If so, consider dropping to 160 after signals fade in the evening. Consider 40m to be only a daytime band at best under present conditions. You might try 60m during the day.

Ground wave on 75 and 160 can work with good quality vertical antennas, but my experience has been that it works best with a salt water ground or with at least a couple of KW over a good radial ground system (I used 2mhz commercially with 2 and 5kw transmitters for a long while and typical daytime range over ocean was about 250 miles. We had a VERY quiet location over a mile from our own tranmitters).

Try an open quarter-wave stub. Remember to take the velocity factor for
the stub line into account when you cut it. Alternately a shorted half
wave stub would be OK.

If you have no test equipment, simply cut the stub when listening to
preferably strong signals on a 2m receiver, and transfer it to the input
of you TV amplifier.

As stated in another post, a single stub is fairly broad. The notch will
be typically 25dB deep on 145MHz, but it will still cause considerable
attenuation of any TV signals around 175MHz. However, it is quick to
make, and it should tell you if you are on the right track for
eliminating the TVI. If necessary, you can improve it.

Two stubs, separated by an electrical quarterwave, are much sharper and
deeper than a single stub.

As has also been mentioned, a 145MHz stub will also remove signals on
odd harmonic frequencies (ie 435 and 725MHz). Any TV around 725MHz?

5914. Wire Receiving Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-31 11:00:33 UTC
From: Spin <noemail@alone.invalid>
Message-ID: <lhl6l.2216$Es4.1832@nwrddc01.gnilink.net>
Source record: 18638

Is it possible to construct a random length receiving antenna by capactive loading it thru a window? Both sides of the window with a glued sheet of copper & random length of wire soldered to the outside copper with a strain relief. Inside copper soldered to wire which is connected to a matching unit. Or two sheets of copper on both sides of a window so that i can use coax or ladder line? What about the feasability of inductive loading in the same manner?

Predicting ground wave distances isn't exactly an 'exact' science by
any means. An 'aproximate' answer is about as good as it gets. Try
'FGQ's program with a very low and a very high efficiency number.
Average it. that'll give you a 'ball-park' figure to play with.

Ofcourse it is feasable. The glass becomes the dielectric of a
capacitor
and there are dipoles made with a series of capacitors in line.
You can also vay the capacitance by sliding one copper sheet to one
side!
Art

"What can I do?"

You are installing an FM receiving antewnna inside. Go for a twinlead dipole about 5 feet long and accept the received signals you get. Range is line of sight so the nearby stations with high antennas will probably be received satisfactorily. MFJ may sell such a dipole readymade.

Best regards, Richard Harrison, KB5WZI

In point of fact, I *do* make measurements like that, and as I said,
it requires "moderate care" and good technique and instrumentation. A
random diode measured with your $5 Harbor Freight DMM isn't going to
hack it. Neither is most of the stuff sold to hams. It is hardly a
"snap", but it *is* within the reach of someone at home with a lot of
time and care to substitute for expensive gear and calibrations
(basically, you have to do your own calibration).

Standard power measuring head on a Agilent power meter is better than
5% at HF, probably in the range of 1% for one head in comparison
measurements over a short time. The 8902 is sort of a special case,
but can do very accurate relative measurements. FWIW, the 8902

calibrates out the measurement head effects.

>
> Scale error demands a full-scale indication to simple keep the error
> contribution down to 0.1% (a 1/10th scale indication would jump that

This oversimplifies a bit. Typically, you'll have some uncertainty that is proportional to the signal measured (e.g. mismatch will affect the signal the same way regardless of level) and some that is absolute, independent of the signal level (e.g. the analog noise in the voltmeter). As you say, bigger signals are easier to measure precisely.. the real limiting factor is the accuracy with which you know the attenuation of the attenuators you're using to get the steps.

With regard to mismatch, if you're interested in tenth dB accuracies, you're going to have to measure the mismatch and account for it. It's not that hard, just tedious. The typical power meter head doesn't change it's Z very much, so once you've measured YOUR head and keep the data around, you're good to go for the future. (and do your tests at the same temperature, don't use the head for a door stop, etc.)

As far as calculating uncertainties.. you bet.. it's not just stacking em up. But that's true of ANY precision measurement, so if one is quoting better than half dB numbers (i.e. if you give any digits to the right of the decimal point) one should be able to back it up with the uncertainty analysis (which is all described on the NIST website and in the tech notes). This isn't hard, it's just tedious. But the whole thing about high quality amateur measurements is you're trading off your time to do tedious extra measurements and analysis in exchange for not sending a cal-lab a check.

The how to do it is all out there. What was "state of the art" for a national laboratory in 1970 is fairly straightforward garage work these days, and, a heck of a lot easier because you've got inexpensive automation for making the measurements and inexpensive computer power for doing the calibration calculations and uncertainty analysis.

The slide 36 discussion refers to measuring a signal at -110dBm, which I would venture to say is well below the levels that most hams will be interested in measuring. And, they are talking about where the source Z is unconstrained. In a typical ham situation, these things probably aren't the case. If you were interested in measuring, for instance, the loss of a piece of coax or the output of a 0dBm buffer amplifier to a tenth of a dB, that's a whole lot easier than a -110dBm signal from some probe into a 8902. The context of this discussion was making measurements of antennas, and for that, one can normally arrange to have decent signal levels, etc. OR, one is interested in relative measurements, rather than absolute calibration. It's a whole lot easier to measure a 0.1 dB difference between two signals.

You suggested 5 alternatives:
ee if you can cook up a method that doesn't hammer you into the

ground. I can anticipate some:

1. Throw a box car of money at the problem;
>>> Or, throw some time at the problem.. this is the classic ham tradeoff.. "I don't have money, but I do have time" It's no different than grinding your own telescope mirrors, building your own Yagi or wire antenna, etc.

2. Buy lab time at NIST;
>>> That's the money thing (and it doesn't require boxcar loads.. perhaps a kilobuck or two.. and for some folks, it's worth it.. although I can't see any amateur radio need. I can see doing it as part of a hobby involving precision, like the folks on time-nuts who operate multiple Cs clocks and build very high performance quartz oscillators for the thrill of getting to 1E-14 or 1E-16 Allan deviation.. Folks who do home nuclear fusion also might avail themselves of pro cal services for their neutron detectors, because there isn't a convenient way of doing home cals, unlike for RF power, where it's at least possible)

3. Write a report that runs to book length (I've carried most of that
water by providing the link above) - or xerox the book that already
exists: "Microwave Theory and Applications," Stephen F. Adam;

>> Or any of a variety of sources. One doesn't need a book for this, but one does need some care in technique and some background knowledge. It's like reading John Strong's book on building scientific instruments (back in the 40s, one built one's physics experimental gear and calibrated it yourself)

4. Do it with precision components employing best practices to the
best achievable accuracy - you will need further instruction into best
practices, however;

5. Ignore reality.

Spin wrote:
> Frequency Range (If Possible), 535-1705 Khz. & 1.8-30 Mhz.

I hope you have a big window. :-) This technique works
well at UHF, fairly well at VHF, not well at HF because
of the necessary physical size.

There is a formula for capacitance C between two plates
given in "The ARRL Handbook".
A is the area of the plates in cm.
d is the spacing of the plates in cm.
Er is the dielectric constant of the insulating
material, in this instance glass.
E0 is the permittivity of free space.

C = A(Er)(E0)/d

The capacitive reactance needs to be relatively low,
e.g. -j10 ohms.

That would be a capacitance of about 0.02 uF at 1 MHz.

Is there more than one VHF FM broadcast band then? I guess 88MHz to 108MHz.

I don't think I've made my problem clear: I don't have space to mount a 1.5m antenna, hence my OP "Modern cars seem to have much shorter aerials ..."

I've got about 75cm of headroom, so I need to use a short antenna, like they have on cars. So how are they made to be short?

Get a copy of the ARRL Antenna book. Look up VHF antenna's. You can make
a 1/4 wave antenna directly or you can add a coil of wire to either end
or the center of a shorter length of wire. The Antenna book will give
you the details and some antenna theory at the same time.

>Like I said in the post you replied to, I have about half this.

Try starting with a twinlead dipole of this length, and shape it into
a near-circle with around 6" between the ends of the arms.

This will give you a vaguely-omnidirectional pattern, using an antenna
which fits into a 2' circle.

<<hi

There never w as any filters just antenna going into a master am,
that had a tone of settings but i don't think anything was build
into the amp to actually filter or notch the current one is a Pico
52 it has gain tilt attenuation fm trap going from memory i
think thats it

but previously no external filters the prev master amp was
blounder tongue seemd to have simular settings

since the reception is so poor now perhaps once they fix/ballance
out the system that might also reduce some 2m interference

good idea you had

>
> Dale W4OP

thanks Mike and Dale, hmm so that is a pickle if it notches
out a TV channel hmmm that would be bad the UHF stations would
also be the most week so i guess then i would be sol

perhaps i'd have to use a commercial notch filter then

it's unsure if by coiedence if the harmonics might fall out on a
few of the unused channels or not

hmm

than again i ponder if the digital tv would simply not be effected by the 10m or 2m rigs, then again could be worse but perhaps digital tv might actually 'save me''

again i appreciate all those that responded i have a lot of good ideas to experiement and try

happy new yrs

If the window can open, I would just run a length of thin magnet
wire and shut the window on it. I think most windows have enough
slack to be able to shut and lock with them down on the magnet
wire.
If the window can't open, I guess that would be a problem.. :/
I'd probably drill a tiny hole in the frame somewhere and run a wire
through.

The whip(s) on my FM receiver(s) seem(s) to demonstrate a complete disregard for polarization, lay it horizontal, it works well, stand it up vertically--it works well, sometimes a positive change in signal can be had, sometimes not, sometimes an improvement--sometimes not. I have not done a thorough study, but it all seems completely random, location, nearby metal objects, structures, etc., most likely, contribute to all this, also ... but, I hazard to guess, that quite often, polarization gets "screwed" up on the way to the receiving antenna.

Currently, I have a 1/2 wave DLM (distributed load monopole -- Robert Vincent) up in the attic which provides input to a homemade preamp utilizing a MMIC device. Most of the time, the preamp is not used ... however, I do kick it in because, I am in a poor location to receive NPR and it makes the difference in being able to receive a low power, local college station satisfactorily.

Of all the antennas I have tried, this just simply works the most satisfactorily for me. It would be possible to construct the DLM in a dipole configuration and run it horizontal, but, like I stated, I just don't have all that much faith in that paying all that much attention to polarization, at FM broadcast freqs, will provide a great benefit(s.)

And, of course, others' mileage may vary ...

But, for a cheap quick fix, the folded dipole, already suggested, helps.

Regards,
JS

Nigel Molesworth wrote:
"I don`t have space to mount a 1.5 m. antenna--."

In any direction? Well Nigel is in luck anyway as a quarterwave antenna worked against a counterpoise or groundplane workes about as well as a halfwave vertical antenna. Automobile antennas work as a vertical over a groundplane of sorts. If the antenna is too short, it picks up less signal but the receiver usually is quiet and has surplus gain so the problem is unimportant.

Only 75 cm or 30 inches is required for 1/4-wavelength which is resonant at 100 MHz over a good ground of the right sort.

As few as two 30-in. wires laid horizontally in opposite directions may serve as a counterpoise to a 30-in. vertical antenna.

Receiving antennas are usually very tolerant but need to be kept away from large noise sources.

Best regards, Richard Harrison, KB5WZI

Source record: 18670

Richard Fry wrote:
> Roy Lewallen's post of Dec 29, 9:45 pm generally supports the points I
> have been writing about.

That surprises me. Apparently I didn't understand your points, which seem to emphasize the importance of considering the field very close to the antenna in evaluating an antenna's performance for long-distance skip communication. The data I posted show clearly that this isn't so, because that strong field at low angles is attenuated to virtually zero well before it can reach the ionosphere. The low elevation angle field close to the antenna is of interest only if the other station is close to the antenna.

> But two observations are due:
>

>
> The last sentence above is incorrect in that I made no such claim. My
> post stated only that radiation from elevation angles as small as one
> degree will reach the ionosophere. See the paste below.

Sorry, I interpreted your postings to state that the surface wave was an important factor to consider in determining the strength of the field from a vertical for working skip communication. If that's not what you meant, then exactly what is the point you were trying to make regarding the importance of considering the surface wave for amateur communication?

> "But that isn't the case -- the relative field over real ground at low
> elevation angles close to the vertical radiator can be very high, and
> will continue onward to produce a long-range skywave. Even radiation
> at an elevation angle of one degree will reach the ionosphere, due to
> earth curvature."

The data I gave shows this to be incorrect. While the field at low angles close to the radiator are very high, they don't "continue outward to produce a long-range skywave". The very low angle field, as I've shown, decays rapidly with distance and is virtually gone well short of the distance needed to reach the ionosphere. From the data, at one degree elevation angle, the surface wave has decayed to nearly zero within 50 miles of the antenna (the difference between sky wave + surface wave and sky wave only is 0.8 dB), and at 7 MHz, within 10

miles. This means that the surface wave makes no contribution to the one degree elevation angle wave reaching the ionosphere. So there's no point in calculating or considering the surface wave if your interest is in ionospheric, or anything other than ground wave, communication.

> A low elevation angle does not include zero degrees (the horizontal
> plane).

Ok.

>> The reported field strengths are in dBi for easy comparison; ...
>
> The term "dBi" is not a unit of field strength. Field strength is a
> voltage existing between two points in space typically one meter
> apart, and is expressed in terms of that voltage with respect to that
> distance, as in volts/meter (V/m).

dBi is a direct expression of field strength, but normalized for power and distance. At any particular distance and power level, for any field strength in V/m there is only one corresponding value of dBi, and vice-versa. I gave the conversion equation in my posting.

> Field strengths can be compared using decibels, but such comparisons
> are referenced to the field strength shown in standard form. For
> example, a field strength of 1,000 ï¿½V/m may be expressed as 60 dBiï¿½V/m.

dBi is more than just dB. It's field strength (in dB) relative to a known standard. That enables direct calculation of field strength in V/m for any power level and distance, given the dBi value.

But that's really beside the point. Anyone with a calculator and the posted equation can quickly convert the table I gave into V/m for whatever power level you'd like. The conclusions are the same.

Since your operation seems to be NVIS rather than ground wave, I highly recommend _Near Vertical Incidence Skywave Communication: Theory, Techniques, and Validation_, by Fiedler and Farmer, published by Worldradio Books. Don't know if it's still in print, but it shouldn't be hard to find a copy on the web.

Roy Lewallen, W7EL

For entertainment we defer to the anonymous Mr. Assembly-wizard and his
cowardly anonymous side kick RP.

You are just a two bit anonymous posting moron that does not contribute
to the news group in any meaningful way. None care what you post.

Having conversations with yourself on Usenet will not endear you to the
normal readers you goofball.
